The C^1 generic diffeomorphism has trivial centralizer

C. Bonatti, S. Crovisier and A. Wilkinson

April 9, 2008

Abstract

Answering a question of Smale, we prove that the space of C^1 diffeomorphisms of a compact manifold contains a residual subset of diffeomorphisms whose centralizers are trivial.

1 Introduction

1.1 The centralizer problem, and its solution in $\text{Diff}^1(M)$

It is a basic fact from linear algebra that any two commuting matrices in $GL(n, \mathbb{C})$ can be simultaneously triangularized. The reason why is that if A commutes with B , then A preserves the generalized eigenspaces of B , and vice versa. Hence the relation $AB = BA$ is quite special among matrices, and one might not expect it to be satisfied very often. In fact, it's not hard to see that the generic pair of matrices A and B generate a free group; any relation in A and B defines a nontrivial subvariety in the space of pairs of matrices, so the set of pairs of matrices that satisfy *no relation* is *residual*: it contains a countable intersection of open-dense subsets. On the other hand, the generic $n \times n$ matrix is diagonalizable and commutes with an n -dimensional space of matrices. That is, a residual set of matrices have large centralizer.

Consider the same sort of questions, this time for the group of C^1 diffeomorphisms $\text{Diff}^1(M)$ of a compact manifold M . If f and g are diffeomorphisms satisfying $fg = gf$, then g preserves the set of orbits of f , as well as all of the smooth and topological dynamical invariants of f , and vice versa. Also in analogy to the matrix case, an easy transversality argument (written in [G, Proposition 4.5] for circle homeomorphisms), shows that *for a generic $(f_1, \dots, f_p) \in (\text{Diff}^r(M))^p$ with $p \geq 2$ and $r \geq 0$, the group $\langle f_1, \dots, f_p \rangle$ is free*. In contrast with the matrix case, however, the generic C^1 diffeomorphism cannot have a large centralizer. This is the content of this paper. Our main result is:

Main Theorem. *Let M be any closed, connected smooth manifold. There is a residual subset $\mathcal{R} \subset \text{Diff}^1(M)$ such that for any $f \in \mathcal{R}$, and any $g \in \text{Diff}^1(M)$, if $fg = gf$, then $g = f^n$, for some $n \in \mathbb{Z}$.*

This theorem¹ gives an affirmative answer in the C^1 topology to the following question, posed by S. Smale. We fix a closed manifold M and consider the space $\text{Diff}^r(M)$ of C^r diffeomorphisms of M , endowed with the C^r topology. The *centralizer* of $f \in \text{Diff}^r(M)$ is defined as

$$Z^r(f) := \{g \in \text{Diff}^r(M) : fg = gf\}.$$

Clearly $Z^r(f)$ always contains the cyclic group $\langle f \rangle$ of all the powers of f . We say that f has *trivial centralizer* if $Z^r(f) = \langle f \rangle$. Smale asked the following:

Question 1 ([Sm1, Sm2]). *Consider the set of C^r diffeomorphisms of a compact manifold M with trivial centralizer.*

1. *Is this set dense in $\text{Diff}^r(M)$?*
2. *Is it residual in $\text{Diff}^r(M)$? That is, does it contain a dense G_δ ?*
3. *Does it contain an open and dense subset of $\text{Diff}^r(M)$?*

¹This result has been announced in [BCW2].

For the case $r = 1$ we now have a complete answer to this question. The theorem above shows that for any compact manifold M , there is a residual subset of $\text{Diff}^1(M)$ consisting of diffeomorphisms with trivial centralizer, giving an affirmative answer to the second (and hence the first) part of Question 1. Recently, with G. Vago, we have also shown:

Theorem. [BCVW] *For any compact manifold M , the set of C^1 diffeomorphisms with trivial centralizer does not contain any open and dense subset.*

This result gives a negative answer to the third part of Question 1; on any compact manifold, [BCVW] exhibits a family of C^∞ diffeomorphisms with large centralizer that is C^1 dense in a nonempty open subset of $\text{Diff}^1(M)$.

The history of Question 1 goes back to the work of N. Kopell [Ko], who gave a complete answer for $r \geq 2$ and the circle $M = S^1$: the set of diffeomorphisms with trivial centralizer contains an open and dense subset of $\text{Diff}^r(S^1)$. For $r \geq 2$ on higher dimensional manifolds, there are partial results with additional dynamical assumptions, such as hyperbolicity [PY1, PY2, Fi] and partial hyperbolicity [Bu1]. In the C^1 setting, Togawa proved that generic Axiom A diffeomorphisms have trivial centralizer. In an earlier work [BCW1], we showed that for $\dim(M) \geq 2$, the C^1 generic conservative (volume-preserving or symplectic) diffeomorphism has trivial centralizer in $\text{Diff}^1(M)$. A more complete list of previous results can be found in [BCW1].

1.2 The algebraic structure and the topology of $\text{Diff}^1(M)$

These results suggest that the topology of the set of diffeomorphisms with trivial centralizer is complicated and motivate the following questions.

- Question 2.**
1. Consider the set of diffeomorphisms whose centralizer is trivial. *What is its interior?*
 2. *Is it a Borel set?* (See [FRW] for a negative answer to this question in the measurable context.)
 3. The set $\{(f, g) \in \text{Diff}^1(M) \times \text{Diff}^1(M) : fg = gf\}$ is closed. *What is its local topology? For example, is it locally connected?*

Beyond just proving the genericity of diffeomorphisms with trivial centralizer, we find a precise collection of dynamical properties of f that imply that $\mathcal{Z}^1(f) = \langle f \rangle$. As an illustration of what we mean by this, consider the Baumslag-Solitar relation $gfg^{-1} = f^n$, where $n > 1$ is a fixed integer. Notice that if this relation holds for some g , then the periodic points of f cannot be hyperbolic. This implies that for the C^1 generic f , there is *no diffeomorphism* g satisfying $gfg^{-1} = f^n$. In this work, we consider the relation $gfg^{-1} = f$. The dynamical properties of f that forbid this relation for $g \notin \langle f \rangle$ are the Large Derivative (LD) and Unbounded Distortion (UD) properties (described in greater detail in the subsequent sections).

Hence the Main Theorem illustrates the existence of links between the dynamics of a diffeomorphism and its algebraic properties as a element of the group $\text{Diff}^1(M)$. In that direction, it seems natural to propose the following (perhaps naive) generalizations of Question 1.

- Question 3.** 1. Consider $G = \langle a_1, \dots, a_k \mid r_1, \dots, r_m \rangle$ a finitely presented group where $\{a_i\}$ is a generating set and r_i are relations. How large is the set of diffeomorphisms $f \in \text{Diff}^r(M)$ such that there is an injective morphism $\rho: G \rightarrow \text{Diff}^r(M)$ with $\rho(a_1) = f$? The Main Theorem implies that this set is meagre if G is abelian (or even nilpotent).
2. Does there exist a diffeomorphism $f \in \text{Diff}^r(M)$ such that, for every $g \in \text{Diff}^r(M)$, the group generated by f and g is either $\langle f \rangle$ if $g \in \langle f \rangle$ or the free product $\langle f \rangle * \langle g \rangle$?
3. Even more, does there exist a diffeomorphism $f \in \text{Diff}^r(M)$ such that, for every finitely generated group $G \in \text{Diff}^r(M)$ with $f \in G$, there is a subgroup $H \subset G$ such that $G = \langle f \rangle * H$?
4. If the answer to either of the two previous items is “yes”, then how large are the corresponding sets of diffeomorphisms with these properties?

1.3 On C^1 -generic diffeomorphisms

Our interest in Question 1 comes also from another motivation. The study of the dynamics of diffeomorphisms from the perspective of the C^1 -topology has made substantial progress in the last decade, renewing hope for a reasonable description of C^1 -generic dynamical systems. The elementary question on centralizers considered here presents a natural challenge for testing the strength of the new tools.

Our result certainly uses these newer results on C^1 -generic dynamics, in particular those related to Pugh’s closing lemma, Hayashi’s connecting lemma, the extensions of these techniques incorporating Conley theory, and the concept of *topological tower* introduced in [BC]. Even so, the Main Theorem is far from a direct consequence of these results; in this subsection, we focus on the new techniques and tools we have developed in the process of answering Question 1.

Our proof of the Main Theorem goes back to the property which is at the heart of most perturbation results specific to the C^1 -topology.

1.3.1 A special property of the C^1 -topology

If we focus on a very small neighborhood of an orbit segment under a differentiable map, the dynamics will appear to be linear around each point; thus locally, iterating a diffeomorphism consists in multiplying invertible linear maps.

On the other hand, the C^1 -topology is the unique smooth topology that is invariant under (homothetical) rescaling. More precisely, consider a perturbation $f \circ g$ of a diffeomorphism f , where g is a diffeomorphism supported in a ball $B(x, r)$ and C^1 -close to the identity. The C^1 -size of the perturbation does not increase if we replace g by its conjugate $h_\lambda g h_\lambda^{-1}$ where h_λ is the homothety of ratio $\lambda < 1$. The new perturbation is now supported on the ball $B(x, r\lambda)$. When λ goes to 0, we just see a perturbation of the linear map $D_x f$.

This shows that local C^1 -perturbation results are closely related to perturbations of linear cocycles. This connection is quite specific to the C^1 -topology: this type of renormalization of a perturbation causes its C^2 -size to increase proportionally to

the inverse of the radius of its support. The rescaling invariance property of the C^1 topology is shared with the Lipschitz topology; however, bi-Lipschitz homeomorphisms do not look like linear maps at small scales.

This special property of the C^1 -topology was first used in the proof of Pugh's closing lemma, and perhaps the deepest part of the proof consists in understanding perturbations of a linear cocycle. Pugh introduced the fundamental, simple idea that, if we would like to perform a large perturbation in a neighborhood of a point x , we can spread this perturbation along the orbit of x and obtain the same result, but by C^1 -small perturbations supported in the neighborhood of an orbit segment. The difficulty in this idea is that, if one performs a small perturbation of f in a very small neighborhood of the point $f^i(x)$, the effect of this perturbation when observed from a small neighborhood of x is deformed by a conjugacy under the linear map Df^i ; this deformation is easy to understand if Df^i is an isometry or a conformal map, but it has no reason in general to be so.

Our result is based on Propositions 5.2 and 6.6, which both produce a perturbation of a linear cocycle supported in the iterates of a cube Q . The aim of Proposition 5.2 is to perturb the derivative Df in order to obtain a large norm $\|Df^n\|$ or $\|Df^{-n}\|$, for a given n and for every orbit that meets a given subcube $\delta Q \subset Q$; the aim of Proposition 6.6 is to obtain a large variation of the jacobian $\det Df^n$, for some integer n and for all the points of a given subcube $\theta Q \subset Q$. The first type of perturbation is connected to the Large Derivative (LD) property, and the second, to the Unbounded Distortion (UD) property.

The main novelty of these two elementary perturbation results is that, in contrast to the case of the closing lemma, whose aim is to perturb a single orbit, our perturbation lemmas will be used to perturb all the orbits of a given compact set. To perturb all orbits in a compact set, we first cover the set with open cubes, and then carry out the perturbation cube-by-cube, using different orbit segments for adjacent cubes. For this reason, we need to control the effect of the perturbation associated to a given cube on the orbits through all of its neighboring cubes.

To obtain this control, for each cube in the cover, we perform a perturbation along the iterates of the cubes until we obtain the desired effect on the derivative, and then we use more iterates of the cube to “remove the perturbation.” By this method, we ensure that the long-term effect of the perturbation on the orbit will be as small as possible in the case of Proposition 6.6, and indeed completely removed in the case of Proposition 5.2. In the latter case, we speak of *tidy perturbations*. These perturbations, which are doing “nothing or almost nothing,” are our main tools.

1.3.2 Perturbing the derivative without changing the topological dynamics

In the proof of the Main Theorem, we show that every diffeomorphism f can be C^1 -perturbed in order to obtain simultaneously the (UD)- and (LD)-properties, which together imply the triviality of the centralizer. However, unlike the (UD)-property, the (LD)-property is not a generic property: to get both properties to hold simultaneously, we have to perform a perturbation that produces the (LD)-property while preserving the (UD)-property.

Our solution consists in changing the derivative of f without changing its topological dynamics. The only context in which an arbitrary perturbation of the derivative of f will not alter its dynamics is one where f is structurally stable. Here f is not assumed to have any kind of stability property, and yet we can realize a substantial effect on the derivative by a perturbation preserving the topological dynamics. For example, starting with an irrational rotation of the torus \mathbb{T}^d , we can obtain, via an arbitrarily C^1 -small perturbation, a diffeomorphism g , conjugate to the original rotation, with the property:

$$\lim_{n \rightarrow \infty} \inf_{x \in \mathbb{T}^d} \sup_{y \in \text{orb}_g(x)} \|Dg^n(y)\| + \|Dg^{-n}(y)\| = \infty.$$

Let us state our result (this is a weak version of Theorem B below):

Theorem. *Let f be a diffeomorphism whose periodic orbits are all hyperbolic. Then any C^1 -neighborhood of f contains a diffeomorphism g such that*

- *g is conjugate to f via a homeomorphism.*
- *g has the large derivative property: for every $K > 0$ there exists n_K such that, for every $n \geq n_K$ and any non-periodic point x :*

$$\sup_{y \in \text{orb}_g(x)} \{\|Dg^n(y)\|, \|Dg^{-n}(y)\|\} > K.$$

As far as we know, this result is the first perturbation lemma which produces a perturbation of the derivative inside the topological conjugacy class of a given diffeomorphism (with the unique hypothesis that all periodic orbits are hyperbolic, which is generic in any topology). In the proof, we construct the perturbation g of f as a limit of tidy perturbations g_n of f which are smoothly conjugate to f . As we think that tidy perturbations will be used in further works, we present them in some detail.

1.3.3 Tidy perturbations

Let f be a diffeomorphism and let U be an open set such that the first iterates \overline{U} , $f(\overline{U})$, \dots , $f^n(\overline{U})$ are pairwise disjoint, for some $n > 0$. Consider a perturbation g of f with support in $V = \bigcup_{i=0}^{n-1} f^i(U)$ that has no effect at all on the orbits crossing V : that is, for every $x \in U$, $f^n(x) = g^n(x)$. In our proof of Theorem B, we construct such perturbations, using the first iterates \overline{U} , $f(\overline{U})$, \dots , $f^i(\overline{U})$, for some $i \in \{0, \dots, n-2\}$, for perturbing f and getting the desired effect on the derivative, and using the remaining iterates $f^{i+1}(\overline{U}), \dots, f^{n-1}(\overline{U})$ for removing the perturbation, bringing the g -orbits of the points $x \in \overline{U}$ back onto their f -orbits. The diffeomorphism g is smoothly conjugate to f via some diffeomorphism that is the identity map outside $\bigcup_{i=0}^{n-1} f^i(U)$. Such a perturbation is called a *tidy perturbation*.

Tidy perturbations require open sets that are disjoint from many of their iterates. To get properties to hold on all non-periodic points, we use such open sets that also cover all the orbits of f , up to finitely many periodic points of low period. Such

open sets, called *topological towers*, were constructed in [BC] for the proof of a connecting lemma for pseudo-orbits. In Section 3.4, we further refine the construction of topological towers; in particular, we prove that it is always possible to construct topological towers disjoint from any compact set with the *wandering orbit property*. The wandering orbit property is a weak form of wandering behavior, satisfied, for example, by nonperiodic points and compact subsets of the wandering set.

In the proof of Theorem B, we construct an infinite sequence (g_i) , where g_i is a tidy perturbation of g_{i-1} , with support in the disjoint n_i first iterates of some open set U_i . We show that, if the diameters of the U_i decrease quickly enough, then the conjugating diffeomorphisms converge in the C^0 -topology to a homeomorphism conjugating the limit diffeomorphism g to f . With a weaker decay to 0 of the diameters of the U_i , it may happen that the conjugating diffeomorphisms converge uniformly to some continuous noninvertible map. In that case, the limit diffeomorphism g is merely semiconjugate to f . This kind of technique has already been used, for instance by M. Rees [R], who constructed homeomorphisms of the torus with positive entropy and semiconjugate to an irrational rotation.

Controlling the effect of successive general perturbations is very hard. For tidy perturbations it is easier to manage the effect of a successive sequence of them, since each of them has no effect on the dynamics. However this advantage leads to some limitations on the effect we can hope for, in particular on the derivative. We conjecture for instance that it is not possible to change the Lyapunov exponents:

Conjecture 1.1. Let $g = hfh^{-1}$ be a limit of tidy perturbations $g_i = h_i f h_i^{-1}$ of f , where the h_i converge to h . Then given any ergodic invariant measure μ of f , the Lyapunov exponents of the measure $h_*(\mu)$ for g are the same as those of μ for f .

To obtain the (LD)-property, we create some oscillations in the size of the derivative along orbits. It seems natural to ask if, on the other hand, one could erase oscillations of the derivative. Let us formalize a question:

Question 4. Let f be a diffeomorphism and assume that Λ is a minimal invariant compact set of f that is uniquely ergodic with invariant measure μ . Assume that all the Lyapunov exponents of μ vanish. Does there exist $g = hfh^{-1}$, a limit of tidy perturbations of f , such that the norm of Dg^n and of Dg^{-n} remain bounded on $h(\Lambda)$?

Such minimal uniquely ergodic sets appear in the C^1 generic setting (among the dynamics exhibited by [BD]).

In this paper, starting with a diffeomorphism f without the (LD)-property, we build a perturbation $g = hfh^{-1}$ as a limit of tidy perturbations and such that g satisfies the (LD)-property. Then the linear cocycles Df over f and Dg over g are not conjugate by a continuous linear cocycle over h .

Question 5. Is there a measurable linear cocycle over h conjugating Dg to Df ?

1.4 Local and global: the structure of the proof of the Main Theorem

The proof of the Main Theorem breaks into two parts, a “local” one and a “global” one. This is also the general structure of the proofs of the main results in [Ko, PY1,

PY2, To1, To2, Bu2]:

- The local part proves that for the generic f , if g commutes with f , then $g = f^\alpha$ on an open and dense subset $W \subset M$, where $\alpha: W \rightarrow \mathbb{Z}$ is a locally constant function.

This step consists in “individualizing” a dense collection of orbits of f , arranging that the behavior of the diffeomorphism in a neighborhood of one orbit is different from the behavior in a neighborhood of any other. Hence g must preserve each of these orbits, which allows us to obtain the function α on these orbits.

This individualization of orbits happens whenever a property of unbounded distortion (UD) holds between certain orbits of f , a property which we describe precisely in the next section. Theorem A shows that the (UD) property holds for a residual set of f .

- The global part consists in proving that for generic f , α is constant. We show that it is enough to verify that the function α is bounded. This would be the case if the derivative Df^n were to take large values on each orbit of f , *for each large n* : the bound on Dg would then forbid α from taking arbitrarily large values. Notice that this property is global in nature: we require large derivative of f^n on each orbit, for each large n .

Because it holds for every large n , this large derivative (LD) property is not generic, although we prove that it is dense. This lack of genericity affects the structure of our proof: it is not possible to obtain both (UD) and (LD) properties just by intersecting two residual sets. Theorem B shows that *among the diffeomorphisms satisfying (UD)*, the property (LD) is dense. This allows us to conclude that the set of diffeomorphisms with trivial centralizer is C^1 -dense.

There is some subtlety in how we obtain a residual subset from a dense subset. Unfortunately we don’t know if the set of diffeomorphisms with trivial centralizer form a G_δ , i.e., a countable intersection of open sets. For this reason, we consider centralizers defined inside of the larger space of bi-Lipschitz homeomorphisms, and we use the compactness properties of this space. The conclusion is that if a C^1 -dense set of diffeomorphisms has trivial centralizer inside of the space of bi-Lipschitz homeomorphisms, then this property holds on a C^1 residual set.

1.5 Perturbations for obtaining the (LD) and (UD) properties

To complete the proof of the Main Theorem, it remains to prove Theorems A and B. Both of these results split in two parts.

- The first part is a local perturbation tool, which changes the derivative of f in a very small neighborhood of a point, the neighborhood being chosen so small that f resembles a linear map on many iterates of this neighborhood.

- In the second part, we perform the perturbations provided by the first part at different places in such a way that the derivative of every (wandering or non-periodic) orbit will be changed in the desirable way. For the (UD) property on the wandering set, the existence of open sets disjoint from all its iterates are very helpful, allowing us to spread the perturbation out over time. For the (LD) property, we need to control every non-periodic orbit. The existence of *topological towers* with very large return time, constructed in [BC], are the main tool, allowing us again to spread the perturbations out over a long time interval.

Acknowledgments

This paper grew out of several visits between the authors hosted by their home institutions. The authors would like to thank the Institut de Mathématiques de Bourgogne, the Northwestern University Math Department, and the Institut Galilée of the Université Paris 13 for their hospitality and support. This work was supported by NSF grants DMS-0401326 and DMS-0701018. We also thank Andrés Navas, who initially called our attention to the Lipschitz centralizer, and who pointed out several references to us.

2 The local and global strategies

In the remaining six sections, we prove the Main Theorem, following the outline in the Introduction. In this section, we reduce the proof to two results, Theorems A and B, that together give a dense set of diffeomorphisms with the (UD) and (LD) properties.

2.1 Background on C^1 -generic dynamics

The space $\text{Diff}^1(M)$ is a Baire space in the C^1 topology. A *residual* subset of a Baire space is one that contains a countable intersection of open-dense sets; the Baire category theorem implies that a residual set is dense. We say that a property holds for the C^1 -generic diffeomorphism if it holds on a residual subset of $\text{Diff}^1(M)$.

For example, the Kupka-Smale Theorem asserts (in part) that for a C^1 -generic diffeomorphism f , the periodic orbits of f are all hyperbolic. It is easy to verify that, furthermore, the C^1 -generic diffeomorphism f has the following property: if x, y are periodic points of f with period m and n respectively, and if their orbits are distinct, then the set of eigenvalues of $Df^m(x)$ and of $Df^n(y)$ are disjoint. If this property holds, we say that the *periodic orbits of f have distinct eigenvalues*.

Associated to any homeomorphism f of a compact metric space X are several canonically-defined, invariant compact subsets that contain the points in X that are recurrent, to varying degrees, under f . Here we will use three of these sets, which are the *closure of the periodic orbits*, denoted here by $\overline{\text{Per}(f)}$, the *nonwandering set* $\Omega(f)$, and the *chain recurrent set* $CR(f)$. By the canonical nature of their construction, the sets $\overline{\text{Per}(f)}$, $\Omega(f)$ and $CR(f)$ are all preserved by any homeomorphism g that commutes with f .

We recall their definitions. The nonwandering set $\Omega(f)$ is the set of all points x such that every neighborhood U of x meets some iterate of U :

$$U \cap \bigcup_{k>0} f^k(U) \neq \emptyset.$$

The chain recurrent set $CR(f)$ is the set of *chain recurrent points* defined as follows. Given $\varepsilon > 0$, we say that a point x is ε -recurrent, and write $x \sim_\varepsilon x$, if there exists an ε -pseudo-orbit, that is a sequence of points x_0, x_1, \dots, x_k , $k \geq 1$ satisfying $d(f(x_i), x_{i+1}) < \varepsilon$, for $i = 0, \dots, k-1$, such that $x_0 = x_k = x$. Then x is *chain recurrent* if $x \sim_\varepsilon x$, for all $\varepsilon > 0$. Conley theory implies that the complement of $CR(f)$ is the union of sets of the form $U \setminus \overline{f(U)}$ where U is an open set which is attracting: $\overline{f(U)} \subset U$. The chain-recurrent set is partitioned into compact invariant sets called the *chain-recurrence classes*: two points $x, y \in CR(f)$ belong to the same class if one can join x to y and y to x by ε -pseudo-orbits for every $\varepsilon > 0$.

It is not difficult to see that for any f , the inclusions $\overline{\text{Per}(f)} \subseteq \Omega(f) \subseteq CR(f)$ hold; there exist examples where the inclusions are strict. For C^1 generic diffeomorphisms f , however, all three sets coincide; $\overline{\text{Per}(f)} = \Omega(f)$ is a consequence of Pugh's closing lemma [Pu], and $\Omega(f) = CR(f)$ was shown much more recently in [BC].

We have additional links between $\Omega(f)$ and the periodic points in the case it has non-empty interior:

Theorem ([BC]). *For any diffeomorphism f in a residual subset of $\text{Diff}^1(M)$, any connected component O of the interior of $\Omega(f)$ is contained in the closure of the stable manifold of a periodic point $p \in O$.*

Conceptually, this result means that for C^1 generic f , the interior of $\Omega(f)$ and the *wandering set* $M \setminus \Omega(f)$ share certain nonrecurrent features. While points in the interior of $\Omega(f)$ all have nonwandering dynamics, if one instead considers the restriction of f to a stable manifold of a periodic orbit $W^s(p) \setminus \mathcal{O}(p)$, the dynamics are no longer recurrent; in the induced topology on the submanifold $W^s(p) \setminus \mathcal{O}(p)$, every point has a *wandering neighborhood* V whose iterates are all disjoint from V . Furthermore, the sufficiently large future iterates of such a wandering neighborhood are contained in a neighborhood of the periodic orbit. While the forward dynamics on the wandering set are not similarly “localized” as they are on a stable manifold, they still share this first feature: on the wandering set, every point has a wandering neighborhood (this time the neighborhood is in the topology on M).

Thus, the results in [BC] imply that for the C^1 generic f , we have the following picture: there is an f -invariant open and dense subset W of M , consisting of the union of the interior of $\Omega(f)$ and the complement of $\Omega(f)$, and densely in W the dynamics of f can be decomposed into components with “wandering strata.” We exploit this fact in our local strategy, outlined in the next section.

2.2 Conditions for the local strategy: the unbounded distortion (UD) properties

In the local strategy, we control the dynamics of the C^1 generic f on the open and dense set $W = \text{Int}(\Omega(f)) \cup (M \setminus \Omega(f))$. We describe here the main analytic properties we use to control these dynamics.

We say that diffeomorphism f satisfies the *unbounded distortion property on the wandering set* ($UD^{M \setminus \Omega}$) if there exists a dense subset $\mathcal{X} \subset M \setminus \Omega(f)$ such that, for any $K > 0$, any $x \in \mathcal{X}$ and any $y \in M \setminus \Omega(f)$ not in the orbit of x , there exists $n \geq 1$ such that:

$$|\log |\det Df^n(x)| - \log |\det Df^n(y)|| > K.$$

A diffeomorphism f satisfies the *unbounded distortion property on the stable manifolds* (UD^s) if for any hyperbolic periodic orbit \mathcal{O} , there exists a dense subset $\mathcal{X} \subset W^s(\mathcal{O})$ such that, for any $K > 0$, any $x \in \mathcal{X}$ and any $y \in W^s(\mathcal{O})$ not in the orbit of x , there exists $n \geq 1$ such that:

$$|\log |\det Df|_{W^s(\mathcal{O})}^n(x)| - \log |\det Df|_{W^s(\mathcal{O})}^n(y)|| > K.$$

Our first main perturbation result is:

Theorem A (Unbounded distortion). *The diffeomorphisms in a residual subset of $\text{Diff}^1(M)$ satisfy the ($UD^{M \setminus \Omega}$) and the (UD^s) properties.*

A variation of an argument due to Togawa [To1, To2] detailed in [BCW1] shows the (UD^s) property holds for a C^1 -generic diffeomorphism. To prove Theorem A, we are thus left to prove that the ($UD^{M \setminus \Omega}$) property holds for a C^1 -generic diffeomorphism. This property is significantly more difficult to establish C^1 -generically than the (UD^s) property. The reason is that points on the stable manifold of a periodic point all have the same future dynamics, and these dynamics are “constant” for all large iterates: in a neighborhood of the periodic orbit, the dynamics of f are effectively linear. In the wandering set, by contrast, the orbits of distinct points can be completely unrelated after sufficiently many iterates.

Nonetheless, the proofs that the ($UD^{M \setminus \Omega}$) and (UD^s) properties are C^1 residual share some essential features, and both rely on the essentially non-recurrent aspects of the dynamics on both the wandering set and the stable manifolds.

2.3 Condition for the global strategy: the large derivative (LD) property

Here we describe the analytic condition on the C^1 -generic f we use to extend the local conclusion on the centralizer of f to a global conclusion.

A diffeomorphism f satisfies the *large derivative property (LD) on a set X* if, for any $K > 0$, there exists $n(K) \geq 1$ such that for any $x \in X$ and $n \geq n(K)$, there exists $j \in \mathbb{Z}$ such that:

$$\sup\{\|Df^n(f^j(x))\|, \|Df^{-n}(f^{j+n}(x))\|\} > K;$$

more compactly:

$$\liminf_{n \rightarrow \infty} \sup_{x \in X} \sup_{y \in \text{orb}(x)} \{Df^n(y), Df^{-n}(y)\} = \infty.$$

Rephrased informally, the (LD) property on X means that the derivative Df^n “tends to ∞ ” *uniformly* on all orbits passing through X . We emphasize that the large

derivative property is a property of the *orbits* of points in X , and if it holds for X , it also holds for all iterates of X .

Our second main perturbation result is:

Theorem B (Large derivative). *Let f be a diffeomorphism whose periodic orbits are hyperbolic. Then, there exists a diffeomorphism g arbitrarily close to f in $\text{Diff}^1(M)$ such that the property (LD) is satisfied on $M \setminus \text{Per}(f)$.*

Moreover,

- f and g are conjugate via a homeomorphism Φ , i.e. $g = \Phi f \Phi^{-1}$;
- for any periodic orbit \mathcal{O} of f , the derivatives of f on \mathcal{O} and of g on $\Phi(\mathcal{O})$ are conjugate (in particular the periodic orbits of g are hyperbolic);
- if f satisfies the $(UD^{M \setminus \Omega})$ property, then so does g ;
- if f satisfies the (UD^s) property, then so does g .

As a consequence of Theorems A and B we obtain:

Corollary 2.1. *There exists a dense subset \mathcal{D} of $\text{Diff}^1(M)$ such that any $f \in \mathcal{D}$ satisfies the following properties:*

- the periodic orbits are hyperbolic and have distinct eigenvalues;
- any component O of the interior of $\Omega(f)$ contains a periodic point whose stable manifold is dense in O ;
- f has the $(UD^{M \setminus \Omega})$ and the (UD^s) properties;
- f has the (LD) property on $M \setminus \text{Per}(g)$.

2.4 Checking that the centralizer is trivial

We now explain why properties (UD) and (LD) together imply that the centralizer is trivial.

Proposition 2.2. *Any diffeomorphism f in the C^1 -dense subset $\mathcal{D} \subset \text{Diff}^1(M)$ given by Corollary 2.1 has a trivial centralizer $Z^1(f)$.*

Proof of Proposition 2.2. Consider a diffeomorphism $f \in \mathcal{D}$. Let $g \in Z^1(f)$ be a diffeomorphism commuting with f , and let $K > 0$ be a Lipschitz constant for g and g^{-1} . Let $W = \text{Int}(\Omega(f)) \cup (M \setminus \Omega(f))$ be the f -invariant, open and dense subset of M whose properties are discussed in Section 2.1.

Our first step is to use the “local hypotheses” $(UD^{M \setminus \Omega})$ and (UD^s) to construct a function $\alpha: W \rightarrow \mathbb{Z}$ that is constant on each connected component of W and satisfies $g = f^\alpha$. We then use the “global hypothesis” (LD) to show that α is bounded on W , and therefore extends to a constant function on M .

We first construct α on the wandering set $M \setminus \Omega(f)$. The basic properties of Lipschitz functions and the relation $f^n g = g f^n$ imply that for any $x \in M$, and any $n \in \mathbb{Z}$, we have

$$|\log \det(Df^n(x)) - \log \det(Df^n(g(x)))| \leq 2d \log K, \quad (1)$$

where $d = \dim M$. On the other hand, f satisfies the $\text{UD}^{M \setminus \Omega(f)}$ property, and hence there exists a dense subset $\mathcal{X} \subset M \setminus \Omega(f)$, each of whose points has unbounded distortion with respect to any point in the wandering set not on the same orbit. That is, for any $x \in \mathcal{X}$, and $y \in M \setminus \Omega(f)$ not on the orbit of x , we have:

$$\limsup_{n \rightarrow \infty} |\log |\det Df^n(x)| - \log |\det Df^n(y)|| = \infty.$$

Inequality (1) then implies that x and $y = g(x)$ lie on the same orbit, for all $x \in \mathcal{X}$, hence $g(x) = f^{\alpha(x)}(x)$. Using the continuity of g and the fact that the points in $M \setminus \Omega(f)$ admit wandering neighborhoods whose f -iterates are pairwise disjoint, we deduce that the map $\alpha: \mathcal{X} \rightarrow \mathbb{Z}$ is constant in the neighborhood of any point in $M \setminus \Omega(f)$. Hence the function α extends on $M \setminus \Omega(f)$ to a function that is constant on each connected component of $M \setminus \Omega(f)$. Furthermore, $g = f^\alpha$ on $M \setminus \Omega(f)$.

We now define the function α on the interior $\text{Int}(\Omega(f))$ of the nonwandering set. Since the periodic orbits of $f \in \mathcal{D}$ have distinct eigenvalues and since g preserves the rate of convergence along the stable manifolds, the diffeomorphism g preserves each periodic orbit of f . Using the (UD^s) condition, one can extend the argument above for the wandering set to the stable manifolds of each periodic orbit (see also [BCW1, Lemma 1.2]). We obtain that for any periodic point p , the diffeomorphism g coincides with a power f^α on each connected component of $W^s(p) \setminus \{p\}$. For $f \in \mathcal{D}$, each connected component O of the interior of $\Omega(f)$ contains a periodic point p whose stable manifold is dense in O . It follows that g coincides with some power f^α of f on each connected component of the interior of $\Omega(f)$.

We have seen that there is a locally constant function $\alpha: W \rightarrow \mathbb{Z}$ such that $g = f^\alpha$ on the f invariant, open and dense subset $W \subset M$. We now turn to the global strategy. Notice that, since f and g commute, the function α is constant along the non-periodic orbits of f . Now $f \in \mathcal{D}$ satisfies the (LD) property. Consequently there exists $N > 0$ such that, for every non-periodic point x , and for every $n \geq N$ there is a point $y = f^i(x)$ such that either $\|Df^n(y)\| > K$ or $\|Df^{-n}(y)\| > K$. This implies that the function $|\alpha|$ is bounded by N : otherwise, α would be greater than N on the invariant open set W of M . This open set contains a non-periodic point x and an iterate $y = f^i(x)$ such that either $\|Df^\alpha(y)\| > K$ or $\|Df^{-\alpha}(y)\| > K$. This contradicts the fact that g and g^{-1} are K -Lipschitz.

We have just shown that $|\alpha|$ is bounded by some integer N . Let Per_{2N} be the set of periodic points of f whose period is less than $2N$, and for $i \in \{-N, \dots, N\}$ consider the set

$$P_i = \{x \in M \setminus \text{Per}_{2N}, g(x) = f^i(x)\}.$$

This is a closed invariant subset of $M \setminus \text{Per}_{2N}$. What we proved above implies that $M \setminus \text{Per}_{2N}$ is the union of the sets P_i , $|i| \leq N$. Moreover any two sets P_i, P_j with $i \neq j$ are disjoint since a point in $P_i \cap P_j$ would be $|i - j|$ periodic for f .

If $\dim(M) \geq 2$, since M is connected and Per_{2N} is finite, the set $M \setminus \text{Per}_{2N}$ is connected. It follows that only one set P_i is non-empty, implying that $g = f^i$ on M . This concludes the proof in this case.

If $\dim(M) = 1$, one has to use that g is a diffeomorphism and is not only Lipschitz: this shows that on the two sides of a periodic orbit of f , the map g coincides with the same iterate of f . This proves again that only one set P_i is nonempty. \square

2.5 From dense to residual: compactness and semicontinuity

The previous results show that the set of diffeomorphisms having a trivial centralizer is dense in $\text{Diff}^1(M)$, but this is not enough to conclude the proof of the Main Theorem. Indeed the dense subset \mathcal{D} in Corollary 2.1 is *not* a residual subset if $\dim(M) \geq 2$: in the appendix we exhibit a nonempty open set in which C^1 -generic diffeomorphisms do not satisfy the (LD)-property.

Fix a metric structure on M . A homeomorphism $f : M \rightarrow M$ is *K-bi-Lipschitz* if both f and f^{-1} are Lipschitz, with Lipschitz norm bounded by K . A homeomorphism that is K -bi-Lipschitz for some K is called a *bi-Lipschitz homeomorphism*, or *lipeomorphism*. We denote by $\text{Lip}^K(M)$ the set of K -bi-Lipschitz homeomorphisms of M and by $\text{Lip}(M)$ the set of bi-Lipschitz homeomorphisms of M . The Arzèla-Ascoli theorem implies that $\text{Lip}^K(M)$ is compact in the uniform (C^0) topology. Note that $\text{Lip}(M) \supset \text{Diff}^1(M)$. For $f \in \text{Lip}(M)$, the set $Z^{\text{Lip}}(f)$ is defined analogously to the C^r case:

$$Z^{\text{Lip}}(f) := \{g \in \text{Lip}(M) : fg = gf\}.$$

In dimension 1, the Main Theorem was a consequence of Togawa's work [To2]. In higher dimension, the Main Theorem is a direct corollary of:

Theorem 2.3. *If $\dim(M) \geq 2$, the set of diffeomorphisms f with trivial centralizer $Z^{\text{Lip}}(f)$ is residual in $\text{Diff}^1(M)$.*

The proof of Theorem 2.3 has two parts.

Proposition 2.4. *If $\dim(M) \geq 2$, any diffeomorphism f in the C^1 -dense subset $\mathcal{D} \subset \text{Diff}^1(M)$ given by Corollary 2.1 has a trivial centralizer $Z^{\text{Lip}}(f)$.*

The proof of this proposition from Theorems A and B is the same as the proof of Proposition 2.2 (see also Lemma 1.2 in [BCW1]).

Proposition 2.5. *Consider the set \mathcal{T} of diffeomorphisms $f \in \text{Diff}^1(M)$ having a trivial centralizer $Z^{\text{Lip}}(f)$. Then, if \mathcal{T} is dense in $\text{Diff}^1(M)$, it is also residual.*

Remark 2.6. The proof of Proposition 2.5 also holds in the C^r topology $r \geq 2$ on any manifold M on which the C^r -generic diffeomorphism has at least one hyperbolic periodic orbit (for example, on the circle, or on manifolds of nonzero Euler characteristic). On the other hand, Theorem 2.3 is false for general manifolds in the C^2 topology, at least for the circle. In fact, a simple folklore argument (see the proof of Theorem B in [N]) implies that for *any* Kupka-Smale diffeomorphism $f \in \text{Diff}^2(S^1)$, the set $Z^{\text{Lip}}(f)$ is *infinite dimensional*. It would be interesting to find out what is true in higher dimensions.

Proof of Proposition 2.5. For any compact metric space X we denote by $\mathcal{K}(X)$ the set of non-empty compact subsets of X , endowed with the Hausdorff distance d_H . We use the following classical fact.

Proposition. *Let \mathcal{B} be a Baire space, let X be a compact metric space, and let $h : \mathcal{B} \rightarrow \mathcal{K}(X)$ be an upper-semicontinuous function. Then the set of continuity points of h is a residual subset of \mathcal{B} .*

In other words, if h has the property that for all $b \in \mathcal{B}$,

$$b_n \rightarrow b \implies \limsup b_n = \bigcap_n \overline{\bigcup_{i>n} h(b_i)} \subseteq h(b),$$

then there is a residual set $\mathcal{R}_h \subset \mathcal{B}$ such that, for all $b \in \mathcal{R}_h$,

$$b_n \rightarrow b \implies \lim d_H(b_n, b) = 0.$$

To prove Proposition 2.5, we note that for a fixed $K > 0$, the set $Z^{\text{Lip}}(f) \cap \text{Lip}^K(M)$ is a closed subset (in the C^0 topology) of the compact metric space $\text{Lip}^K(M)$. This is a simple consequence of the facts that $Z^{\text{Lip}}(f)$ is defined by the relation $fgf^{-1}g^{-1} = \text{id}$, and that composition and inversion are continuous. Thus there is well-defined map h_K from $\text{Diff}^1(M)$ to $\mathcal{K}(\text{Lip}^K(M))$, sending f to $h_K(f) = Z^{\text{Lip}}(f) \cap \text{Lip}^K(M)$. It is easy to see that h_K is upper-semicontinuous: if f_n converges to f in $\text{Diff}^1(M)$ and $g_n \in h_K(f_n)$ converges uniformly to g then g belongs to $h_K(f)$.

Let $\mathcal{R}_K \subset \text{Diff}^1(M)$ be the set of points of continuity of h_K ; it is a residual subset of $\text{Diff}^1(M)$, by Proposition 2.5. Let $\mathcal{R}_{\text{Hyp}} \subset \text{Diff}^1(M)$ be the set of diffeomorphisms such that each $f \in \mathcal{R}_{\text{Hyp}}$ has at least one hyperbolic periodic orbit (the C^1 Closing Lemma implies that \mathcal{R}_{Hyp} is residual). Finally, let

$$\mathcal{R} = \mathcal{R}_{\text{Hyp}} \cap \bigcap_{K=1}^{\infty} \mathcal{R}_K.$$

Assuming that \mathcal{T} is dense in $\text{Diff}^1(M)$, we claim that the set \mathcal{R} is contained in \mathcal{T} , implying that \mathcal{T} is residual. To see this, fix $f \in \mathcal{R}$, and let $f_n \rightarrow f$ be a sequence of diffeomorphisms in \mathcal{T} converging to f in the C^1 topology. Let $g \in Z^{\text{Lip}}(f)$ be a K -bi-Lipschitz homeomorphism satisfying $fg = gf$. Since h_K is continuous at f , there is a sequence $g_n \in Z^{\text{Lip}}(f_n)$ of K -bi-Lipschitz homeomorphisms with $g_n \rightarrow g$ in the C^0 topology. The fact that $f_n \in \mathcal{T}$ implies that the centralizer $Z^{\text{Lip}}(f_n)$ is trivial, so there exist integers m_n such that $g_n = f^{m_n}$.

If the sequence (m_n) is bounded, then passing to a subsequence, we obtain that $g = f^m$, for some integer m . If the sequence (m_n) is not bounded, then we obtain a contradiction as follows. Let x be a hyperbolic periodic point of f , of period p . For n large, the map f_n has a periodic orbit x_n of period p , and the derivatives $Df_n^p(x_n)$ tend to the derivative $Df^p(x)$. But then $|\log \|Df_n^{m_n}\||$ tends to infinity as $n \rightarrow \infty$. This contradicts the fact that the diffeomorphisms $f_n^{m_n} = g_n$ and $f_n^{-m_n} = g_n^{-1}$ are both K -Lipschitz, concluding the proof. \square

3 Perturbing the derivative without changing the dynamics

In order to prove Theorem B, one needs to perturb a diffeomorphism f and change the dynamical properties of its derivative without changing its topological dynamics: the resulting diffeomorphism is still conjugate to f . We develop in this section an important technique for the proof, which we call *tidy perturbations* of the dynamics.

3.1 Tidy perturbations

Definition 3.1. Let $f : M \rightarrow M$ be a homeomorphism and let $X \subset M$. We say that a homeomorphism g is a *tidy perturbation of f supported on X* if:

1. $g(x) = f(x)$, for all $x \in M \setminus X$,
2. if $x \in M \setminus X$ and $f^m(x) \in M \setminus X$, for some $m \geq 1$, then $g^m(x) = f^m(x)$;
3. if $x \in M \setminus X$ and $g^m(x) \in M \setminus X$, for some $m \geq 1$, then $g^m(x) = f^m(x)$;
4. for all $x \in M$, there exists $m \in \mathbb{Z}$ such that $f^m(x) \in M \setminus \overline{X}$;
5. for all $x \in M$, there exists $m \in \mathbb{Z}$ such that $g^m(x) \in M \setminus \overline{X}$.

Note that this definition is symmetric in f and g .

Lemma 3.2. *If g is a tidy perturbation of f supported on X , then g is conjugate to f by a homeomorphism φ such that $\varphi = \text{id}$ on $M \setminus (X \cap f(X))$. Furthermore, if g and f are diffeomorphisms, then φ is a diffeomorphism as well.*

Proof. Given f and a tidy perturbation g of f supported on X , we construct a homeomorphism φ as follows. Property 4 of tidy perturbations implies that for each $x \in M$, there exists an integer m_x such that $f^{m_x}(x) \in M \setminus \overline{X}$. We set $\varphi(x) = g^{-m_x} f^{m_x}(x)$.

Then φ is well-defined, for suppose that $f^{m_1}(x) \notin \overline{X}$ and $f^{m_2}(x) \notin \overline{X}$, for some integers $m_1 < m_2$. Let $y = f^{m_1}(x)$. Then $y \notin \overline{X}$, and $f^{m_2-m_1}(y) = f^{m_2}(x) \notin \overline{X}$. Property 2 of tidy perturbations implies that $g^{m_2-m_1}(y) = f^{m_2-m_1}(y)$; in other words, $g^{-m_1} f^{m_1}(x) = g^{-m_2} f^{m_2}(x)$. Hence the definition of $\varphi(x)$ is independent of the integer m_x . In particular $g \circ \varphi = \varphi \circ f$.

To see that φ is continuous, note that for every $x \in M$, if $f^m(x) \notin \overline{X}$, then there exists a neighborhood U of x such that $f^m(U) \cap \overline{X} = \emptyset$. Hence $\varphi = g^{-m} \circ f^m$ on U . This implies that φ is a local homeomorphism.

Let φ^- be the local homeomorphism obtained by switching the roles of f and g . Clearly φ^- is the inverse of φ , so that φ is a homeomorphism. If f and g are diffeomorphisms, it is clear from the construction of φ that φ is a diffeomorphism.

Properties 1 and 2 of tidy perturbations imply that for any point $x \in M \setminus (X \cap f(X))$, we have $f^{m_x}(x) = g^{m_x}(x)$. This gives $\varphi = \text{id}$ on $M \setminus (X \cap f(X))$. \square

Each the tidy perturbations we will consider is supported in the union of successive disjoint iterates of an open set. In that case, the characterization of tidy perturbations is much easier, as explained in the next lemma:

Lemma 3.3. *Let f be a homeomorphism, $U \subset M$ an open set, and $m \geq 1$ an integer such that the iterates $\overline{U}, f(\overline{U}), \dots, f^m(\overline{U})$ are pairwise disjoint.*

Let g be a homeomorphism such that:

- *$g = f$ on the complement of the union $X = \bigcup_{i=0}^{m-1} f^i(U)$, and*
- *for all $x \in U$, $f^m(x) = g^m(x)$.*

Then g is a tidy perturbation of f supported on X .

Proof. Property 1 of tidy perturbations is immediate; property 4 is as well, since $\overline{U}, f(\overline{U}), \dots, f^m(\overline{U})$ are pairwise disjoint.

Let x be a point in $M \setminus X$ whose f -orbit enters and leaves X , and let $i > 0$ be its first entry in X ; then $f^i(x) = g^i(x)$ by the first hypothesis on g . The f -orbit of x leaves X at $f^{m+i}(x) = g^{m+i}(x)$, by the second hypothesis on g . Proceeding inductively on the successive entrances and exits of the f -orbit of x we get that $g^n(x) = f^n(x)$ for every integer n such that $f^n(x) \in M \setminus X$, proving Property 2 of tidy perturbations.

There is a neighborhood V of \overline{U} such that $f = g$ on $V \setminus U$. It follows that $f(U) = g(U)$. Inductively, we see that $g^i(U) = f^i(U)$ for $i \in \{1, \dots, m\}$. This shows that the hypotheses of the lemma still are satisfied if we switch the roles of f and g . This implies Properties 3 and 5 of tidy perturbations. \square

If g is a small C^1 -perturbation of f that is a tidy perturbation supported in the disjoint union $\bigcup_{i=0}^{m-1} f^i(U)$, it is tempting to think that the conjugating diffeomorphism φ must be C^1 -close to the identity as well. This is not always the case. The derivative Dg is a small perturbation of Df but for $x \in U$ and $i \in \{1, \dots, m\}$, the maps $Df^i(x)$ and $Dg^i(x)$ could be very different. There is however a straightforward *a priori* bound for $D\varphi$:

Lemma 3.4. *Let f be a diffeomorphism, $U \subset M$ an open set and $m \geq 1$ an integer such that the iterates $\overline{U}, f(\overline{U}), \dots, f^m(\overline{U})$ are pairwise disjoint. Suppose that g is a tidy perturbation of f supported on $X = \bigcup_{i=0}^{m-1} f^i(\overline{U})$ and that $\varphi : M \rightarrow M$ is the diffeomorphism such that $g = \varphi \circ f \circ \varphi^{-1}$ and $\varphi = \text{id}$ on $M \setminus X$.*

Then

$$\max\{\|D\varphi\|, \|D\varphi^{-1}\|\} \leq C^m,$$

where $C = \sup\{\|Dg\|, \|Dg^{-1}\|, \|Df\|, \|Df^{-1}\|\}$.

Proof. For every $x \in M$ there exists $i \in \{0, \dots, m\}$ such that $f^i(x) \notin \overline{X}$, so that φ coincides with $g^{-i}f^i$ and $g^{-i+m}f^{i-m}$ in a neighborhood of x . We conclude by noting that either $2i$ or $2(m-i)$ is less than m . \square

3.2 Sequences of tidy perturbations

The aim of this section is to control the effect of infinitely many successive tidy perturbations g_i of a diffeomorphism f and to give a sufficient condition for the sequence g_i to converge to a diffeomorphism g conjugate to f by a homeomorphism.

Lemma 3.5. *Let f be a diffeomorphism and $\varepsilon, C > 0$ be constants such that for every g with $d_{C^1}(f, g) < \varepsilon$, we have $\|Dg\|, \|Dg^{-1}\| < C$. Consider:*

- $(U_i)_{i \geq 1}$, a sequence of open subsets of M ,
- $(m_i)_{i \geq 1}$, a sequence of positive integers,
- $(\varepsilon_i)_{i \geq 1}$, a sequence of positive numbers such that $\sum \varepsilon_i < \varepsilon$,
- $(g_i)_{i \geq 0}$, a sequence of diffeomorphisms such that $g_0 = f$ and for each $i \geq 1$,
 - the sets $\overline{U_i}, g_{i-1}(\overline{U_i}), \dots, g_{i-1}^{m_i}(\overline{U_i})$ are pairwise disjoint,
 - g_i is a tidy ε_i -perturbation of g_{i-1} , supported in $\bigcup_{k=0}^{m_i-1} g_{i-1}^k(U_i)$,
- $(\rho_i)_{i \geq 1}$, a sequence of positive numbers such that $g_{i-1}^k(U_i)$ has diameter bounded by ρ_i , for $k \in \{0, \dots, m_i\}$.

Denote by φ_i the diffeomorphism such that $g_i = \varphi_i \circ g_{i-1} \circ \varphi_i^{-1}$ and $\varphi_i = \text{id}$ on $M \setminus \bigcup_{k=1}^{m_i-1} g_{i-1}^k(U_i)$. Let $\Phi_i = \varphi_i \circ \dots \circ \varphi_1$ and $M_i = \prod_{k=1}^i C^{m_k}$. If one assumes that

$$\sum_{i \geq 1} \rho_i M_{i-1} < \infty,$$

then

1. (g_i) converges in the C^1 metric to a diffeomorphism g with $d_{C^1}(f, g) < \varepsilon$,
2. for all $i < j$ one has $d_{\text{unif}}(\Phi_j \Phi_i^{-1}, \text{id}) < \sum_{k=i+1}^j \rho_k$,
3. (Φ_i) converges uniformly to a homeomorphism Φ satisfying $g = \Phi f \Phi^{-1}$.

Remark 3.6. The uniform metric d_{unif} on continuous self-maps on M in part 3 of this lemma is not complete for the space of homeomorphisms of M ; to avoid confusion, we denote by d_{C^0} the complete metric defined by:

$$d_{C^0}(f, g) = d_{\text{unif}}(f, g) + d_{\text{unif}}(f^{-1}, g^{-1}).$$

One difficulty in the proof of Lemma 3.5, which explains the role of M_i , is to control the distances $d_{\text{unif}}(\Phi_i^{-1} \Phi_j, \text{id})$.

Proof. The first conclusion is clear. Since $\Phi_j \Phi_i^{-1} = \varphi_j \circ \dots \circ \varphi_{i+1}$, the second one is immediate from the hypothesis that φ_i is a tidy perturbation and the fact that the connected components of the support of φ_i have diameter less than ρ_i . The hypothesis $\sum_{k \geq 1} \rho_k < \infty$ implies that $(\Phi_i)_{i \in \mathbb{N}}$ is a Cauchy sequence and converges to a continuous map Φ satisfying $g\Phi = \Phi f$. Finally, the a priori bound in Lemma 3.4 implies that $\|D\Phi_i^{-1}\| < M_i$, so that

$$\sup_{d(x,y) < \rho_i} d(\Phi_{i-1}^{-1}(x), \Phi_{i-1}^{-1}(y)) < \rho_i M_{i-1}.$$

But for any x , we have $d(x, \varphi_i(x)) < \rho_i$. So the previous calculation implies $d(\Phi_{i-1}^{-1}(x), \Phi_i^{-1}(x)) < \rho_i M_{i-1}$. By hypothesis, $\sum_{i \geq 1} \rho_i M_{i-1} < \infty$, which implies that $(\Phi_i^{-1})_{i \in \mathbb{N}}$ is a Cauchy sequence in the d_{unif} metric. Hence (Φ_i^{-1}) converges as $i \rightarrow \infty$ to the inverse of Φ and so Φ is a homeomorphism. \square

3.3 Topological towers

For each tidy perturbation we construct in this paper, we will use an open set with many disjoint iterates. The large number of iterates will allow us to spread the effects of the perturbation out over a large number of steps, effecting a large change in the derivative with a small perturbation. For these perturbations to have a global effect, we need to have most orbits in M visit U . The technique of *topological towers*, developed in [BC], allows us to choose U to have many disjoint iterates, while simultaneously guaranteeing that most orbits visit U .

Theorem 3.7 (Topological towers, [BC], Théorème 3.1). *For any integer $d \geq 1$, there exists a constant $\kappa_d > 0$ such that for any integer $m \geq 1$ and for any diffeomorphism f of a d -dimensional manifold M , whose periodic orbits of period less than $\kappa_d m$ are hyperbolic, there exists an open set U and a compact subset $D \subset U$ having the following properties:*

- *Any point $x \in M$ that does not belong to a periodic orbit of period $< m$ has an iterate $f^i(x)$ in the interior of D .*
- *The sets $\overline{U}, f(\overline{U}), \dots, f^{m-1}(\overline{U})$ are pairwise disjoint.*

Moreover, the connected components of \overline{U} can be chosen with arbitrarily small diameter.

3.4 Towers avoiding certain sets

In constructing our sequence (g_i) of tidy perturbations, we need to ensure that the effects of the $(i+1)$ st perturbations do not undo the effects of the i th perturbation. In addition, we aim to produce large derivative without affecting unbounded distortion. For these reasons, it is desirable to choose the towers in the tidy perturbations to avoid certain subsets in M . It is not possible to choose a tower avoiding an arbitrary subset, but it turns out that certain sets with a *wandering orbit property* can be avoided. We now define this property.

Definition 3.8. Let $N, J \geq 1$ be integers. An (N, J) -wandering cover of a compact set Z is a finite cover \mathcal{U} of Z such that every $V \in \mathcal{U}$ has N iterates $f^j(V), f^{j+1}(V), \dots, f^{j+N-1}(V)$ with $j \in \{1, \dots, J\}$ that are disjoint from Z .

Definition 3.9. Let f be a homeomorphism and $Z \subset M$ be a compact set.

Z has the (N, J) -wandering orbit property if it has an (N, J) -wandering cover.

Z has the N -wandering orbit property if it has the (N, J) -wandering orbit property for some $J \geq 1$.

Z has the wandering orbit property if it has the N -wandering orbit property, for every $N \geq 1$.

The next lemma explains that topological towers can be constructed avoiding any compact set with the wandering orbit property.

Lemma 3.10. *Suppose that the periodic orbits of f are all hyperbolic.*

For all $m_1, m_2 \geq 1$, and $\rho > 0$, if Z is any compact set with the m_1 -wandering orbit property, then there exists an open set $U \subset M$ with the following properties:

1. The diameter of each connected component of \overline{U} is less than ρ .
2. The iterates $\overline{U}, f(\overline{U}), \dots, f^{m_1-1}(\overline{U})$ are disjoint from the set Z .
3. The iterates $\overline{U}, f(\overline{U}), \dots, f^{m_1+m_2-1}(\overline{U})$ are pairwise disjoint.
4. There is a compact set $D \subset U$ such that every nonperiodic point $x \in M$ has an iterate in D .

This will be proved at the end of this subsection.

Remark 3.11. • If Z has the (N, J) -wandering orbit property, then for every $\rho > 0$, there is an (N, J) -wandering cover all of whose elements have diameter less than ρ .

- If Z has the (N, J) -wandering orbit property, then so does $f(Z)$.
- More generally, if Z has the (N, J) -wandering orbit property for f , and $g = \Phi f \Phi^{-1}$, then $\Phi(Z)$ has the (N, J) -wandering orbit property for g .

Lemma 3.12. 1. If X is any compact set such that the iterates $X, f(X), \dots, f^{m+N}(X)$ are pairwise disjoint, then $\bigcup_{i=0}^{m-1} f^i(X)$ has the (N, m) -wandering orbit property.

2. If x is any point whose period lies in $(N + 1, \infty]$, then $\{x\}$ has the $(N, 1)$ -wandering orbit property.
3. If x is any nonperiodic point, then $\{x\}$ has the wandering orbit property.
4. Any compact subset $Z \subset \mathcal{W}^s(\text{orb}(p)) \setminus \text{orb}(p)$ has the wandering orbit property, for any hyperbolic periodic point p .
5. Any compact subset of the wandering set $M \setminus \Omega(f)$ of f has the wandering orbit property.

Proof. 1), 2) and 3) are easy. To prove 4), we consider $Z \subset \mathcal{W}^s(\text{orb}(p)) \setminus \text{orb}(p)$, for some hyperbolic periodic point p . Let \mathcal{N} be a neighborhood of the orbit of p that is disjoint from Z . There exists $m > 0$ such that $f^n(Z) \subset \mathcal{N}$ for any $n \geq m$. Given N , there is a covering \mathcal{V} of Z such that, for every $V \in \mathcal{V}$, the sets $f^m(V), \dots, f^{m+N}(V)$ are all contained in \mathcal{N} . Then \mathcal{V} is an (N, m) -wandering cover of Z .

Finally we prove 5). If Z is a compact subset of $M \setminus \Omega(f)$ then every point $z \in Z$ has finitely many returns in Z . So for every $N > 0$ and every $x \in Z$ there is a neighborhood U_x and an integer $j_x > 0$ such that $f^{j_x}(U_x), \dots, f^{j_x+N-1}(U_x)$ are disjoint from Z . Extracting a finite cover U_{x_i} and choosing $J = \max_i j_{x_i}$ we get an (N, J) -wandering cover. \square

Lemma 3.13. Suppose Z has the (N, J) -wandering orbit property and W has the $(2N + J, K)$ -wandering orbit property. Then $Z \cup W$ has the $(N, K + 2J + 2N)$ wandering orbit property.

If Z has the N -wandering orbit property and W has the wandering orbit property, then $Z \cup W$ has the N -wandering orbit property.

If Z and W both have the wandering orbit property, then $Z \cup W$ has the wandering orbit property.

Proof. The second two claims follow from the first. To prove the first, fix a (N, J) -wandering cover \mathcal{U}_Z of Z and a $(2N + J, K)$ -wandering cover \mathcal{V}_W of W with the property that, for every $V \in \mathcal{V}_W$ and every $i \in \{0, \dots, N + K - 1\}$, if $f^i(V)$ intersects Z , then $f^i(V)$ is contained in an element of \mathcal{U}_Z . Let \mathcal{V}_Z be an (N, J) -wandering cover of Z such that, for every $V \in \mathcal{V}_Z$ and every $i \in \{0, \dots, N + J - 1\}$, if $f^i(V)$ intersects W , then $f^i(V)$ is contained in an element of \mathcal{V}_W . We claim that $\mathcal{V}_Z \cup \mathcal{V}_W$ is an $(N, K + 2J + 2N)$ -wandering cover of $Z \cup W$:

- Consider first $V \in \mathcal{V}_W$. As \mathcal{V}_W is a $(2N + J, K)$ -wandering cover of W , there exists $k \in \{1, \dots, K\}$ such that $f^k(V), \dots, f^{k+2N+J-1}(V)$ are disjoint from W . If $f^k(V), \dots, f^{k+N-1}(V)$ are disjoint from Z , then they are disjoint from $W \cup Z$ which is what we want. Otherwise, there exists $V' \in \mathcal{U}_Z$ and $j \in \{1, \dots, N - 1\}$ such that $f^{k+j}(V) \subset V'$. Now there exists $i \in \{1, \dots, J\}$ such that $f^i(V'), \dots, f^{i+N-1}(V')$ are disjoint from Z ; let $j' = k + i + j \in \{1, \dots, K + J + N - 1\}$. Then $f^{j'+i+j}(V), \dots, f^{j'+i+j+N-1}(V)$ are disjoint from $Z \cup W$.
- Now consider $V \in \mathcal{V}_Z$. As \mathcal{V}_Z is a (N, J) -wandering cover of W , there exists $j \in \{1, \dots, J\}$ such that $f^j(V), \dots, f^{j+N-1}(V)$ are disjoint from Z . If $f^j(V), \dots, f^{j+N-1}(V)$ are disjoint from W , then they are also disjoint from $W \cup Z$, which is what we want. Otherwise, there exists $V' \in \mathcal{V}_W$ and $i \in \{1, \dots, N - 1\}$ such that $f^{i+j}(V) \subset V'$. By the previous case, we know there exists $k \in \{1, \dots, K + J = N - 1\}$ such that the iterates $f^k(V'), \dots, f^{k+N-1}(V')$ are disjoint from $Z \cup W$; hence $j' = i + j + k \in \{1, \dots, K + 2N + 2J - 1\}$, and the iterates $f^{j'}(V), \dots, f^{j'+N-1}(V)$ are disjoint from $Z \cup W$.

□

Proof of Lemma 3.10. Let $m_1, m_2 \geq 1$ and $\rho > 0$ be given. Let Z be a compact set with the m_1 -wandering property, and let \mathcal{U} be an (m_1, J) -wandering cover of Z . Let U_0 be an open set given by Theorem 3.7 with the following properties:

- for each connected component O of $\overline{U_0}$ and each $j \in \{0, \dots, m_1 + J - 1\}$, the diameter of $f^j(O)$ is less than ρ ;
- for each component O of $\overline{U_0}$, if $f^i(O) \cap Z \neq \emptyset$, for some $i \in \{0, \dots, m_1 - 1\}$, then $f^i(O)$ is contained in some element of \mathcal{U} ;
- the iterates $\overline{U_0}, f(\overline{U_0}), \dots, f^{2m_1+m_2+J-1}(\overline{U_0})$ are pairwise disjoint;
- there is a compact set $D_0 \subset U_0$ such that every nonperiodic point $x \in M$ has an iterate in D_0 .

For each component O of $\overline{U_0}$, either the first m_1 iterates $O, f(O), \dots, f^{m_1-1}(O)$ are disjoint from Z , or one of these iterates $f^i(O)$ is contained in an element of \mathcal{U} . In the latter case, there exists a $j \in \{1, \dots, m_1 + J - 1\}$ such that the iterates $f^j(O), \dots, f^{j+m_1-1}(O)$ are disjoint from Z . In either case, there exists an iterate $f^j(O)$ of O , $j \in \{0, \dots, m_1 + J - 1\}$ of diameter less than ρ , whose first m_1 iterates are disjoint from Z . Selecting one such iterate $f^j(O)$ for each component of $\overline{U_0}$ and

taking the union of the $f^j(U_0 \cap O)$ over all the components O , we obtain our desired set U . The set D is obtained by intersecting the first $2m_1 + m_2 + J - 1$ iterates of D_0 with the components of U and taking their union. One hence obtain the conclusions 1, 2 and 4.

The sets of the form $f^{j+k}(U_0 \cap O)$, where the sets $f^j(U_0 \cap O)$ define U and $k \in \{0, \dots, m_1 - 1\}$, are pairwise disjoint, since $\overline{U_0}$ is disjoint from its $2m_1 + m_2 + J - 1$ first iterates. This gives conclusion 3 and ends the proof of the lemma. \square

3.5 Linearizing the germ of dynamics along a nonperiodic orbit

In this subsection we present an elementary tool which will be used to construct perturbations of a diffeomorphism f using perturbations of linear cocycles.

Lift of f by the exponential map. Let M be a compact manifold endowed with a Riemannian metric. Denote by $\exp: TM \rightarrow M$ the exponential map associated to this metric, and by $R > 0$ the radius of injectivity of the exponential map: for every $x \in M$ the exponential map at x induces a diffeomorphism $\exp_x: B_x(0, R) \rightarrow B(x, R)$ where $B_x(0, R) \subset T_x M$ and $B(x, R)$ are the balls of radius R centered at $0_x \in T_x M$ and at x , respectively. It is important for our purposes to notice that the derivative $D_x \exp_x$ can be identified with the identity map of $T_x M$.

Let f be a diffeomorphism and let $C > 1$ be a bound for $\|Df\|$ and for $\|Df^{-1}\|$. For each vector $u \in T_x M$ with $\|u\| < R$ and $d(f(x), f(\exp_x(u))) < R$, we define

$$\tilde{f}_x(u) = \exp_{f(x)}^{-1}(f(\exp_x(u))).$$

This formula defines a diffeomorphism $\tilde{f}: U \rightarrow V$ where

$$U = \{(x, u) \in TM \mid \|u\| < R \quad \text{and} \quad d(f(x), f(\exp_x(u))) < R\}$$

$$V = \{(x, u) \in TM \mid \|u\| < R \quad \text{and} \quad d(f^{-1}(x), f^{-1}(\exp_x(u))) < R\}.$$

The sets U and V are neighborhoods of the zero-section of the tangent bundle, both containing the set of vectors whose norm is bounded by $C^{-1}R$. We denote by $\tilde{f}_x: U_x \rightarrow V_{f(x)}$ the induced diffeomorphism on $U_x = U \cap T_x M$.

For every $n \in \mathbb{Z}$ we let U^n be the domain of definition of \tilde{f}^n , we let $V_n = \tilde{f}^n(U_n)$ and we let $\tilde{f}_x^n: U_{x,n} \rightarrow V_{f^n(x),n}$ be the induced map on the fibers.

Linearizing coordinates of \tilde{f} along an orbit. The map \tilde{f}^n defines a germ of the dynamics in a neighborhood of the zero section. The differential Df is also a homeomorphism of TM that induces a continuous family of linear diffeomorphisms on the fibers.

For $n \geq 0$, we let $\psi_n = Df^n \circ \tilde{f}^{-n}: V_n \rightarrow TM$ and $\psi_{x,n}: V_{x,n} \rightarrow T_x M$ be the induced maps. We have the following properties:

- For every integer n , the family $\{\psi_{x,n}\}_{x \in M}$ is a compact family of C^1 diffeomorphisms depending continuously (in the C^1 -topology) on x . Indeed, $\{\tilde{f}_x^{-n}\}_{x \in M}$ and $\{Df_x^n\}_{x \in M}$ are uniformly continuous families of diffeomorphisms.

- The derivative of the diffeomorphism $\psi_{x,n}$ at the zero vector 0_x is the identity map:

$$D_{0_x}(\psi_{x,n}) = Id_{T_x M}.$$

- For every $x \in M$ the family of diffeomorphisms $\{\psi_{f^n(x),n}\}_{n \in \mathbb{N}}$ are linearizing coordinates along the orbit of x ; more precisely, we have the following commutative diagram:

$$\begin{array}{ccccccc} \cdots & \xrightarrow{\tilde{f}} & T_{f^{-1}(x)}M & \xrightarrow{\tilde{f}} & T_x M & \xrightarrow{\tilde{f}} & \cdots & \xrightarrow{\tilde{f}} & T_{f^n(x)}M \\ & & \downarrow \text{id} & & \downarrow \psi_{f(x),1} & & & & \downarrow \psi_{f^n(x),n} \\ \cdots & \xrightarrow{Df} & T_{f^{-1}(x)}M & \xrightarrow{Df} & T_x M & \xrightarrow{Df} & \cdots & \xrightarrow{Df} & T_{f^n(x)}M \end{array}.$$

Perturbations of the linearized dynamics. Given a point $x \in M$ we consider the derivative of f along the orbit $\text{orb}_f(x)$ of x as being a diffeomorphism of the (non-compact, non-connected) manifold $TM|_{\text{orb}_f(x)}$ endowed with the Euclidean metric on the fibers. Now we will consider perturbations of Df in $\text{Diff}^1(TM|_{\text{orb}_f(x)})$ in the corresponding C^1 -topology.

Lemma 3.14. *Let f be a diffeomorphism of a compact manifold. For every pair $0 < \tilde{\varepsilon} < \varepsilon$ and every $n > 0$ there exists $\rho > 0$ with the following property.*

Consider an open set U whose iterates $f^i(U)$, $i \in \{0, \dots, n\}$, are pairwise disjoint. Fix a point $x \in M$ and assume that U is contained in $B(x, \rho)$; let $\tilde{U} = \exp_x^{-1}(U)$. Then we have the following.

1. *For every $i \in \{0, \dots, n\}$, the map $\Psi_{f^i(x),i} = \psi_{f^i(x),i} \circ \exp_{f^i(x)}^{-1}$ induces a diffeomorphism from $f^i(U)$ onto $Df^i(\tilde{U})$ such that*

$$\max\{\|D\Psi_{f^i(x),i}\|, \|D\Psi_{f^i(x),i}^{-1}\|, |\det D\Psi_{f^i(x),i}|, |\det D\Psi_{f^i(x),i}^{-1}|\} < 2.$$

2. *For every perturbation \tilde{g} of Df with support in $\bigcup_{i=0}^{n-1} Df^i(\tilde{U})$ such that $d_{C^1}(\tilde{g}, Df) < \tilde{\varepsilon}$, let g be the map defined by*

- $g(y) = f(y)$ if $y \notin \bigcup_{i=0}^{n-1} f^i(U)$
- $g(y) = \Psi_{f^{i+1}(x),i+1}^{-1} \circ \tilde{g} \circ \Psi_{f^i(x),i}(y)$ if $y \in f^i(U)$, $i \in \{0, \dots, n-1\}$.

Then the map $g: M \rightarrow M$ is a diffeomorphism. It is a perturbation of f with support in $\bigcup_{i=0}^{n-1} f^i(U)$ such that $d_{C^1}(g, f) < \varepsilon$.

3. *If furthermore \tilde{g} is a tidy perturbation of Df , then g is a tidy perturbation of f .*

Proof. The unique nontrivial statement in this lemma is the fact that g is an ε perturbation of f if \tilde{g} is an $\tilde{\varepsilon}$ perturbation of Df . The proof of this is a simple calculation using the facts that:

- the derivative $D_{0_x}(\exp_x)$ is an isometry of $T_x M$,
- the derivative $D_{0_x}\psi_{x,i}$ is the identity for all x and i ,
- the family $\{\psi_{x,i}, x \in M, 0 \leq i \leq n\}$ induces a compact family of C^1 -diffeomorphisms on the balls $B(0_x, \frac{R}{C^n})$ having 0_x as a fixed point.

□

4 (LD) property: reduction to a perturbation result in towers

In this section, we show how to reduce the proof of Theorem B to the following perturbative result. Its proof is deferred to Section 5.

Theorem B' (Large derivative by perturbation). *For any $d \geq 1$ and any $C, K, \varepsilon > 0$, there exists an integer $n_0 = n_0(C, K, \varepsilon) \geq 1$ with the following property. Consider any diffeomorphism f of a d -dimensional manifold M with $\|Df\|, \|Df^{-1}\| < C$ and any $n \geq n_0$. Let $N = 2^{d+1}n$. Then there exists $\rho_0 = \rho_0(n, f, K, \varepsilon) > 0$ such that,*

- *for any open set U with diameter $< \rho_0$ and where the iterates $\overline{U}, f(\overline{U}), \dots, f^{N-1}(\overline{U})$ are pairwise disjoint,*
- *for any compact set $\Delta \subset U$,*

there exists $g \in \text{Diff}^1(M)$ such that

- *the C^1 distance from f to g is less than ε ;*
- *g is a tidy perturbation of f with support in $U \cup f(U) \cup \dots \cup f^{N-1}(U)$;*
- *for any $x \in \Delta$ there exists $j \in \{0, \dots, N - n\}$ such that*

$$\max\{\|Dg^n(g^j(x))\|, \|Dg^{-n}(g^{j+n}(x))\|\} > K.$$

4.1 Our shopping list for the proof of Theorem B

Let M be a compact manifold with dimension d . Consider a diffeomorphism f whose periodic orbits are hyperbolic, a constant $\varepsilon > 0$, a sequence (K_i) that tends to $+\infty$ (for instance $K_i = i$) and a constant $C > 0$ that bounds the norms of Dg and Dg^{-1} , for any diffeomorphism g that is ε -close to f in the C^1 -distance.

Our perturbation g of f will emerge as the limit of a sequence of perturbations $g_0 = f, g_1, g_2, \dots$. Each perturbation g_i will satisfy a large derivative property for an interval of times $[n_i, n_{i+1} - 1]$. The objects involved at step i in the construction are:

- g_i , the perturbation, and ε_i , the C^1 distance from g_i to g_{i-1} .
- $[n_i, n_{i+1} - 1]$, the interval of time for which prescribed large derivative for g_i occur, and K_i , the magnitude of large derivative created for these iterates.
- U_i , an open set such that the iterates $g_{i-1}^k(\overline{U_i})$, $k \in \{0, \dots, m_i\}$ are pairwise disjoint, where $m_i = 2^{d+1}(n_i + n_1 + 1 + \dots + n_{i+1} - 1)$. The perturbation g_i of g_{i-1} is supported in the union of these iterates and is tidy with respect to their union. Φ_i is the C^1 conjugacy between g_i and f such that $\Phi_i \circ \Phi_{i-1}^{-1}$ is supported in $\cup_{k=1}^{m_i-1} g_{i-1}^k(U_i)$. The integer $M_i = \prod_{k=1}^i C^{m_k}$ bounds the C^1 norm of the conjugacy Φ_i .

- $\rho_i > 0$, an upper bound on the diameter of the first m_i iterates of U_i under g_{i-1} .
- D_i , a compact set contained in U_i that meets every aperiodic g_{i-1} -orbit (and hence also every aperiodic orbit of the tidy perturbation g_i).
- Δ_i , a compact set with $D_i \subset \text{int}\Delta_i \subset \Delta_i \subset U_i$. Large derivative will occur for g_i in the first m_i iterates of Δ_i .
- Z_i , a compact set, x_i , a point, and N_i , an iterate, such that property (UD) holds for f between x_i and points of Z_i in time less than N_i .

Some objects in this construction are fixed prior to the iterative construction of the perturbations, and others are chosen concurrently with the perturbations. Thus we have two types of choices, a priori and inductive, and they are chosen in roughly the following order:

- *a priori choices:* $\varepsilon_i, n_i, Z_i, x_i, N_i$;
- *inductive choices:* $\rho_i, U_i, D_i, \Delta_i, g_i$.

4.2 A priori choices

4.2.1 Choice of $\varepsilon_i, n_i, m_i, M_i$

We first describe how to select inductively the positive numbers ε_i and the integers n_i . We initially choose $\varepsilon_1 < \varepsilon/2$ and $n_1 = n_0(C, 2K_1, \varepsilon_1)$, according to Theorem B'. Now given (ε_i, n_i) , we let

$$\varepsilon_{i+1} = \min\{\varepsilon_i/2, \frac{K_{i-1}}{4n_i C^{n_i-1}}\} \quad \text{and} \quad n_{i+1} = n_0(C, 2K_{i+1}, \varepsilon_{i+1}).$$

With these definitions we have for any $\ell \geq 1$,

$$\sum_{k \geq \ell} \varepsilon_k < 2\varepsilon_\ell < \varepsilon.$$

From this it follows that the sequence of perturbations $(g_i)_{i \in \mathbb{N}}$ such that $d_{C^1}(g_{i-1}, g_i) < \varepsilon_i$ and $g_0 = f$ will have a limit $g_i \rightarrow g$ as $i \rightarrow \infty$ that is a diffeomorphism satisfying $d_{C^1}(f, g) < \varepsilon$. The bound for ε_i is justified by the following lemma which allows us to pass to g the Large Derivative Property satisfied by g_i .

Lemma 4.1. *Suppose that $\varepsilon_{i+1} < \frac{K_{i-1}}{4n_i C^{n_i-1}}$. Then, for any $n \leq n_i$ and any sequences of matrices A_1, \dots, A_n and B_1, \dots, B_n satisfying:*

- $\|A_k\|, \|A_k^{-1}\|, \|B_k\|, \|B_k^{-1}\| < C$ for $k \in \{1, \dots, n\}$,
- $\|A_k - B_k\|, \|A_k^{-1} - B_k^{-1}\| < 4\varepsilon_{i+1}$ for $k \in \{1, \dots, n\}$,
- $\max\{\|A_n \cdots A_1\|, \|(A_n \cdots A_1)^{-1}\|\} > 2K_{i-1}$,

we have:

$$\max\{\|B_n \cdots B_1\|, \|(B_n \cdots B_1)^{-1}\|\} > K_{i-1}.$$

Proof. Without loss of generality we may assume that $\|A_n \dots A_1\| > 2K_{i-1}$. We have:

$$\begin{aligned} \|A_n \dots A_1\| - \|B_n \dots B_1\| &\leq \sum_{j=1}^n \|A_n \dots A_{j+1} \cdot (A_j - B_j) \cdot B_{j-1} \dots B_1\| \\ &\leq 4n\varepsilon_{i+1}C^{n-1} \leq 4n_i\varepsilon_{i+1}C^{n_i-1} \\ &< K_{i-1}, \text{ by our choice of } \varepsilon_i. \end{aligned}$$

We obtain the desired conclusion: $\|B_{n_i} \dots B_1\| > \|A_{n_i} \dots A_1\| - K_{i-1} > K_{i-1}$. \square

4.2.2 Choice of x_i , Z_i and N_i

Assume f has the unbounded distortion property on the wandering set $(UD^{M \setminus \Omega})$ and on the stable manifolds (UD^s) . In this section we choose a countable family of pairs (x_i, Z_i) where Z_i is a compact set disjoint from the orbit of x_i which will be used for testing the $(UD^{M \setminus \Omega})$ and the (UD^s) -properties of the perturbations g_i we will construct.

By definition of the $(UD^{M \setminus \Omega})$ -property there exists a countable and dense subset $\mathcal{X}^{M \setminus \Omega} \subset M \setminus \Omega(f)$ such that, for any $K > 0$, any $x \in \mathcal{X}^{M \setminus \Omega}$ and any $y \in M \setminus \Omega(f)$ not in the orbit of x , there exists $n \geq 1$ such that:

$$|\log |\det Df^n(x)| - \log |\det Df^n(y)|| > K.$$

For every $x \in \mathcal{X}^{M \setminus \Omega}$ we choose a countable set \mathcal{Z}_x of compact subsets of $M \setminus \Omega_f$ disjoint from the orbit of x and covering the complement in $M \setminus \Omega$ of the orbit of x . We define

$$\mathcal{Z}^{M \setminus \Omega} = \{(x, Z) | x \in \mathcal{X}^{M \setminus \Omega}, Z \in \mathcal{Z}_x\}.$$

By definition of the (UD^s) -property, for any hyperbolic periodic orbit \mathcal{O} , there exists a dense countable subset $\mathcal{X}^{\mathcal{O}} \subset W^s(\mathcal{O}) \setminus \mathcal{O}$ such that, for any $K > 0$, any $x \in \mathcal{X}^{\mathcal{O}}$ and any $y \in W^s(\mathcal{O})$ not in the orbit of x , there exists $n \geq 1$ such that:

$$|\log |\det Df_{|W^s(\mathcal{O})}^n(x)| - \log |\det Df_{|W^s(\mathcal{O})}^n(y)|| > K.$$

For every $x \in \mathcal{X}^{\mathcal{O}}$ we choose a countable set \mathcal{Z}_x of compact subsets of $W^s(\mathcal{O})$ disjoint from the orbit of x and covering the complement in $W^s(\mathcal{O})$ of the orbit of x . We define

$$\mathcal{Z}^{\mathcal{O}} = \{(x, Z) | x \in \mathcal{X}^{\mathcal{O}}, Z \in \mathcal{Z}_x\}.$$

We set

$$\mathcal{Z}^s = \bigcup_{\mathcal{O} \in \text{Per}(f)} \mathcal{Z}^{\mathcal{O}}, \text{ and } \mathcal{Z} = \mathcal{Z}^{M \setminus \Omega} \sqcup \mathcal{Z}^s \text{ the disjoint union of } \mathcal{Z}^{M \setminus \Omega} \text{ and } \mathcal{Z}^s.$$

Since, by hypothesis, the periodic orbits of f are all hyperbolic, the set of periodic orbits is countable. Consequently \mathcal{Z} is a countable set.

For each pair $(x, Z) \in \mathcal{Z}$, we will need to verify that our perturbations preserve countably many conditions of the form

$$|\log |\det Dg_i^n(x)| - \log |\det Dg_i^n(y)|| > L_i, \quad \text{for every } y \in \Phi_i(Z),$$

where L_i is a sequence of natural numbers tending to ∞ . To this end, we fix an enumeration $\{(x_i, Z_i)\}_{i \in \mathbb{N}}$ of the disjoint union $\bigsqcup_{n \in \mathbb{N}} \mathcal{Z}$; each pair $(x, Z) \in \mathcal{Z}$ appears infinitely many times as a pair (x_{i_k}, Z_{i_k}) in this choice of indexing.

We now fix a sequence of integers N_i as follows:

- If $(x_i, Z_i) \in \mathcal{Z}^{M \setminus \Omega}$ then we fix N_i such that for every $y \in Z_i$ there is $n \in \{1, \dots, N_i\}$ with

$$|\log |\det Df^n(x_i)| - \log |\det Df^n(y)|| > K_i + 4d \log M_i.$$

- If $(x_i, Z_i) \in \mathcal{Z}^{\mathcal{O}}$ for some periodic orbit \mathcal{O} then we fix N_i such that for every $y \in Z_i$ there exists $n \in \{1, \dots, N_i\}$ with

$$|\log |\det Df_{|W^s(\mathcal{O})}^n(x_i)| - \log |\det Df_{|W^s(\mathcal{O})}^n(y)|| > K_i + 4d \log M_i.$$

The M_i appears in these expressions because i will index the i th perturbation in our construction, and the effects of the previous perturbations on the (UD) property will be taken into account. The number M_i^2 bounds the effect of conjugacy by Φ_i on the derivative.

We set $Y_{i,0} = \bigcup_{k=0}^{N_i} f^k(Z_i \cup \{x_i\})$. Lemma 3.12 implies that the sets $Y_{i,0}$ have the wandering orbit property for f .

4.3 Inductive hypotheses implying Theorem B

We now describe conditions on the inductively-chosen objects that must be satisfied and explain how they imply the conclusion of Theorem B. In a later subsection we explain how these choices can be made so that the inductive conditions are satisfied.

4.3.1 Conditions on ρ_i so that (Φ_i) converges

According to Lemma 3.5, the diffeomorphisms Φ_i (conjugating g_i to f) converge uniformly to a homeomorphism Φ (conjugating g to f) provided the following conditions hold.

$$\rho_i < 2^{-1} \min\{\rho_{i-1}, M_{i-1}^{-1}\}. \quad (2)$$

4.3.2 Conditions on ρ_i preserving prolonged visits to towers

Our perturbation at step i will produce prescribed large derivative for g for orbits visiting the compact set Δ_i . In order to verify that g has the (LD) property, we will need to know that every nonperiodic orbit for g visits each set Δ_i , which imposes the following condition on the sequence (ρ_i) :

$$\rho_{i+1} < 2^{-1} \inf_{k \in \{0, \dots, m_i\}} d(g_i^k(D_i), M \setminus g_i^k(\Delta_i)). \quad (3)$$

The (LD) property on g will be proved in the next subsection by using the following lemma.

Lemma 4.2. *Assume furthermore that condition (3) holds. Then for every i and any $y \in M \setminus \text{Per}(g)$, there exists an integer t such that*

$$g^t(y) \in \Delta_i \quad \text{and} \quad g_i^t(x) \in D_i,$$

where $x = \Phi_i \circ \Phi^{-1}(y)$. For all $k \in \{0, \dots, m_i\}$, we also have $g^{t+k}(y) \in g_i^k(\Delta_i)$.

Proof. Fix $j \geq i$. Let y be a non-periodic point for g_j and $x = \Phi_i \circ \Phi_j^{-1}(y)$. For any n , we have $g_j^n(y) = \Phi_j \circ \Phi_i^{-1}g_i^n(x)$. The point x is not periodic for g_i , since y is not periodic for g_j and y is the image of x under the conjugacy between g_i and g_j .

By our hypothesis on D_i , there exists t such that $g_i^t(x) \in D_i$. The hypothesis (3) on ρ_i implies that $\Phi_j \circ \Phi_i^{-1}(g_i^k(D_i)) \subset g_j^k(\Delta_i)$ for $k \in \{0, \dots, 0, \dots, m_i\}$, since, by Lemma 3.5, $d_{\text{unif}}(\Phi_j \circ \Phi_i^{-1}, \text{id}) < \sum_{k=i+1}^j \rho_k < 2\rho_{i+1}$. This implies that $g_j^{n+k}(y) \in g_i^k(\Delta_i)$.

Now consider $y \in M$ that is not periodic for g . Let $x = \Phi_i \circ \Phi^{-1}(y)$. For every $j \geq i$, we set $y_j = \Phi_j \circ \Phi_i^{-1}(x)$; observe that $y_j \rightarrow y$ as $j \rightarrow \infty$. The previous argument implies there exists a t such that for every j and every $k \in \{0, \dots, 0, \dots, m_i\}$, we have $g_j^{t+k}(y_j) \in g_i^k(\Delta_i)$; compactness of Δ_i implies that $g^{t+k}(y) \in g_i^k(\Delta_i)$. \square

4.3.3 Conditions on ρ_i , U_i and g_i for the (LD) property

The next lemma imposes one more requirement on ρ_i, U_i and on the derivative Dg_i in order to obtain property (LD).

Lemma 4.3 (Final conditions for (LD)). *Suppose further that:*

- For every $x, y \in M$,

$$d(x, y) < 2\rho_i \Rightarrow \|Dg_{i-1}(x) - Dg_{i-1}(y)\| < \varepsilon_{i+1}. \quad (4)$$

- The support of g_{i+1} is disjoint from the support of g_i :

$$\overline{U}_{i-1}, \dots, g_{i-1}^{m_{i-1}-1}(\overline{U}_{i-1}), \overline{U}_i, \dots, g_i^{m_i-1}(\overline{U}_i) \text{ are pairwise disjoint.} \quad (5)$$

- For any $n \in [n_i, n_{i+1} - 1]$ and $x \in \Delta_i$, there is $j \in \{0, \dots, m_i - n\}$ such that

$$\max\{\|Dg_i^n(g_i^j(x))\|, \|Dg_i^{-n}(g_i^{j+n}(x))\|\} > 2K_i. \quad (6)$$

Then g has the large derivative (LD) property.

Proof. Let g be the limit of the g_i . Let K be a large positive number and choose i_0 such that $K_{i_0} > K$. We claim that for every $y \in M \setminus \text{Per}(g)$, and for every $n \geq n_{i_0}$, there exists an integer $j > 0$ such that

$$\max\{\|Dg(g^j(y))\|, \|Dg^{-n}(g^{j+n}(y))\|\} > K.$$

Fix such an $n \geq n_{i_0}$, and choose $i \geq i_0$ such that $n \in [n_i, n_{i+1} - 1]$. Let $y \in M \setminus \text{Per}(g)$. Let $x = \Phi_i \circ \Phi^{-1}(y)$. Note that $x \in M \setminus \text{Per}(g_i)$, so by our hypothesis on D_i , there exists an integer t such that $g_i^t(x) \in D_i$. Lemma 4.2 implies

that $g^t(y) \in \Delta_i$. Since the (LD) property is a property of orbits, it suffices to assume that $y \in \Delta_i$ and $x = \Phi_i \circ \Phi^{-1}(y) \in D_i$.

Now $x \in D_i \subset \Delta_i$ implies there exists $j \in \{0, \dots, m_i - n\}$ such that

$$\max\{\|Dg_i^n(g_i^j(x))\|, \|Dg_i^{-n}(g_i^{j+n}(x))\|\} > 2K_i.$$

For any $k \in \{0, \dots, m_i - 1\}$, we have

$$\begin{aligned} & \|Dg(g^k(y)) - Dg_i(g_i^k(x))\| \\ & \leq \|Dg(g^k(y)) - Dg_{i+1}(g^k(y))\| + \|Dg_{i+1}(g^k(y)) - Dg_i(g_i^k(x))\| \\ & \leq 2\varepsilon_{i+2} + \|Dg_{i+1}(g^k(y)) - Dg_i(g^k(y))\| + \|Dg_i(g^k(y)) - Dg_i(g_i^k(x))\|, \end{aligned}$$

where we have used the fact that the C^1 distance from g to g_{i+1} is bounded by $\sum_{k \geq i+2} \varepsilon_k < 2\varepsilon_{i+2}$.

We next bound the remaining terms in the inequality. Since $g^k(y) = \Phi \circ \Phi_i^{-1}(g_i^k(x))$ and $d_{\text{unif}}(\Phi \circ \Phi_i^{-1}, \text{id}) < 2\rho_{i+1}$, the hypothesis (6) implies that

$$\|Dg_i(g^k(y)) - Dg_i(g_i^k(x))\| < \varepsilon_{i+2}.$$

By Lemma 4.2, we know that for $k \in \{0, \dots, m_i - 1\}$, the point $g^k(y)$ belongs to the set $g_i^k(\Delta_i)$. Since the support of g_{i+1} is disjoint from $g_i^k(U_i)$, which contains $g_i^k(\Delta_i)$, we obtain that g_{i+1} and g_i agree in a neighborhood of $g^k(y)$, for $k \in \{0, \dots, m_i - 1\}$. From this it follows that $\|Dg_{i+1}(g^k(y)) - Dg_i(g^k(y))\| = 0$.

We conclude that

$$\|Dg(g^k(y)) - Dg_i(g_i^k(x))\| \leq 3\varepsilon_{i+2}.$$

But now Lemma 4.1 and the Chain Rule imply that

$$\max\{\|Dg^n(g^j(y))\|, \|Dg^{-n}(g^{j+n}(y))\|\} > K_i.$$

□

4.3.4 The derivative at the periodic orbits is preserved

Let \mathcal{O} be a periodic orbit of f . Note that its image by Φ_i should be disjoint from $\overline{U_{i+1}}, \dots, g_i(\overline{U_{i+1}})$ for i large. In particular, the maps g_{i+1} and g_i coincide in a neighborhood of the periodic orbit $\Phi_i(\mathcal{O})$. This proves that $\Phi(\mathcal{O}) = \Phi_i(\mathcal{O})$ and that Dg coincides with Dg_i at points of $\Phi(\mathcal{O})$. Since g_i and f are conjugate by the diffeomorphism Φ_i , we conclude that the derivatives of f on \mathcal{O} and of g on $\Phi(\mathcal{O})$ are conjugate.

4.3.5 Conditions on U_i for preserving the (UD) property

We assume here that f satisfies the unbounded distortion (UD) property on the stable manifolds and on the wandering set, and we consider the sequences (x_i) , (Z_i) , (N_i) and $(Y_{i,0})$ defined in Subsection 4.2.2. Let

$$Y_i = \bigcup_{k=0}^{N_i} g_i^k(\Phi_i(Z_i \cup \{x_i\})) = \Phi_i(Y_{i,0}).$$

We introduce the following condition

$$\text{The sets } \overline{U}_i, \dots, g_{i-1}^{m_i}(\overline{U}_i) \text{ are disjoint from } \cup_{k=1}^{i-1} Y_k. \quad (7)$$

Lemma 4.4. *If in addition hypothesis (7) is satisfied, then g has the unbounded distortion properties $(UD)^{M \setminus \Omega}$ and $(UD)^s$.*

Proof. We prove that g has property $(UD)^{M \setminus \Omega}$; the proof of $(UD)^s$ is similar. Recall the dense set $\mathcal{X}^{M \setminus \Omega}$ in $M \setminus \Omega(f)$ used to define (x_i) and (Z_i) . Clearly $\Phi(\mathcal{X}^{M \setminus \Omega})$ is dense in $M \setminus \Omega(g)$.

Fix $x \in \Phi(\mathcal{X}^{M \setminus \Omega})$ and $y \in M \setminus \Omega(g)$ that are not on the same orbit. Let $K > 0$ be some large constant. We claim that there exists $i \in \mathbb{N}$ such that:

- $\Phi^{-1}(x) = x_i$,
- $\Phi^{-1}(y) \in Z_i$ (and we set $y_i = \Phi^{-1}(y)$),
- $K_i > K$.

Such an i exists because $\Phi^{-1}(y) \in M \setminus (\Omega(f) \cup \text{orb}_f(x))$ and so, by definition of \mathcal{Z}_x , there exists $Z \in \mathcal{Z}_x$ containing $\Phi^{-1}(y)$. The pair (x, Z) appears as (x_i, Z_i) for infinitely many values of i . For i sufficiently large, we have $K_i > K$, which proves the claim.

By definition of N_i , there exists $n \in \{1, \dots, N_i\}$ such that

$$|\log |\det Df^n(x_i)| - \log |\det Df^n(y_i)|| > K_i + 4d \log M_i.$$

Since $g_i = \Phi_i \circ f \circ \Phi_i^{-1}$, and $\|D\Phi_i\|$ and $\|D\Phi_i^{-1}\|$ are both bounded by M_i , we obtain that

$$|\log |\det Dg_i^n(\Phi_i(x_i))| - \log |\det Dg_i^n(\Phi_i(y_i))|| > K_i.$$

Our assumption on the support of the tidy perturbations implies that for every $j > i$, g_j is a tidy perturbation of g_{j-1} whose support is disjoint from the compact set Y_i . This implies that g_j and g_i coincide in a neighborhood of the points $\Phi_i(x_i), g_i(\Phi_i(x_i)), \dots, g^{N_i}(\Phi_i(x_i))$ and $\Phi_i(y_i), g_i(\Phi_i(y_i)), \dots, g^{N_i}(\Phi_i(y_i))$. In particular:

- $\Phi_j(x_i) = \Phi_i(x_i)$ and $\Phi_j(y_i) = \Phi_i(y_i)$. Since the points $\Phi_j(x_i)$ and $\Phi_j(y_i)$ converge to x and y when $j \rightarrow \infty$, it follows that $\Phi_i(x_i) = x$ and $\Phi_i(y_i) = y$.
- $Dg_i^n(\Phi_i(x_i)) = Dg_j^n(x)$ and $Dg_i^n(\Phi_i(y_i)) = Dg_j^n(y)$.

It follows that, for $j \geq i$,

$$|\log |\det Dg_j^n(x)| - \log |\det Dg_j^n(y)|| \geq K_i,$$

Since Dg_j^n tends to Dg^n as $j \rightarrow \infty$, it follows that

$$|\log |\det Dg^n(x)| - \log |\det Dg^n(y)|| \geq K_i > K,$$

which concludes the proof of the $(UD)^{M \setminus \Omega}$ property for g . The proof of the $(UD)^s$ property is completely analogous. □

4.4 Satisfying the inductive hypotheses

To finish the proof of Theorem B (assuming Theorem B'), we are left to explain how to construct inductively $\rho_i, U_i, D_i, \Delta_i$ and g_i satisfying the properties stated at Section 4.1 and properties (2), (3), (4), (5), (6) and (7). For the construction we require the following extra property:

$$\text{The sets } g_{i-1}^j(\overline{U_i}) \text{ for } j \in \{0, \dots, m_i + m_{i+1} - 1\} \text{ are pairwise disjoint.} \quad (8)$$

In the following we assume that all the objects have been constructed up to $\rho_i, U_i, D_i, \Delta_i, g_i$, and we will construct $\rho_{i+1}, U_{i+1}, D_{i+1}, \Delta_{i+1}, g_{i+1}$.

The constant ρ_{i+1} . We choose ρ_{i+1} satisfying:

1. ρ_{i+1} is strictly less than the numbers $\rho_0(n, g_i, 2K_{i+1}, \varepsilon_{i+1})$ given by Theorem B' for $n_{i+1} \leq n < n_{i+2}$;
2. $\rho_{i+1} < 2^{-1} \min\{\rho_i, M_i^{-1}\}$,
3. $\rho_{i+1} < 2^{-1} \inf_{k \in \{0, \dots, m_i\}} d(g_i^k(D_i), M \setminus g_i^k(\Delta_i))$.
4. ρ_{i+1} is less than the Lebesgue number associated to Dg_i for ε_{i+2} , so that, for every $x, y \in M$, if $d(x, y) < 2\rho_{i+1}$, then $\|Dg_i(x) - Dg_i(y)\| < \varepsilon_{i+2}$.

In particular conditions (2), (3) and (4) are satisfied by ρ_{i+1} .

The sets $U_{i+1}, D_{i+1}, \Delta_{i+1}$. Observe that $Y_k = \Phi_k(Y_{k,0}) = \Phi_i(Y_{k,0})$ for $k \leq i$ have the wandering orbit property for g_i because $Y_{k,0}$ have the wandering orbit property for f . By induction property (8) is satisfied by U_i and implies that the sets $g_i^j(\overline{U_i})$ for $j \in \{0, \dots, m_i + m_{i+1} - 1\}$ are pairwise disjoint. By Lemma 3.12, the set $\bigcup_{j=0}^{m_i-1} g_i^j(\overline{U_i})$ has the m_{i+1} -wandering orbit property and so Lemma 3.13 implies that $\bigcup_{k=0}^i Y_k \cup \bigcup_{j=0}^{m_i-1} g_i^j(\overline{U_i})$ has the m_{i+1} -wandering orbit property. Lemma 3.10 gives an open set U_{i+1} and a compact set $D_{i+1} \subset U_{i+1}$ such that

1. the diameter of each connected component of $g_i^j(\overline{U_{i+1}})$, $j \in \{0, \dots, m_{i+1}\}$ is less than ρ_{i+1} ;
2. the sets $g_i^j(\overline{U_{i+1}})$, $j \in \{0, \dots, m_{i+1} - 1\}$, are disjoint from the sets Y_k , $k \leq i$, and from the sets $g_i^j(\overline{U_i})$, $j \in \{0, \dots, m_{i+1} - 1\}$;
3. the sets $g_i^j(\overline{U_{i+1}})$ for $j \in \{0, \dots, m_{i+1} + m_{i+2} - 1\}$ are pairwise disjoint;
4. every nonperiodic point $x \in M$ has an iterate in D_{i+1} .

In particular, conditions (5), (7) and (8) are satisfied by U_{i+1} . We next fix some compact set $\Delta_{i+1} \subset U_{i+1}$ containing D_{i+1} in its interior.

The perturbation g_{i+1} . For each $n \in \{n_{i+1}, \dots, n_{i+2} - 1\}$, we will make a tidy perturbation $g_{n,i+1}$ producing the large derivative at the n th iterate. Furthermore, these perturbations will have pairwise disjoint support.

To do this, we partition $\{0, 1, \dots, m_{i+1} - 1\}$ into intervals of the form $I_n = \{\alpha_n, \dots, \alpha_{n+1} - 1\}$, $n_{i+1} \leq n < n_{i+2}$, where $\alpha_n = 2^{d+1}(n_{i+1} + \dots + n - 1)$. This is possible since $m_{i+1} = 2^{d+1}(n_{i+1} + (n_{i+1} + 1) + \dots + n_{i+2} - 1)$.

The sets $g_i^j(\overline{U_{i+1}})$ for $j \in I_n$ are pairwise disjoint and have a diameter less than $\rho_0(n, g_i, 2K_{i+1}, \varepsilon_{i+1})$. Hence, we can apply Theorem B' to obtain a tidy perturbation $g_{n,i+1}$ of g_i with support in $\bigcup_{j \in I_n} g_i^j(U_{i+1})$ such that $d_{C^1}(g_{n,i+1}, g_i) < \varepsilon_{i+1}$ and for any $x \in g_i^{\alpha_n}(\Delta_{i+1})$, there exists $j \in \{\alpha_n, \dots, \alpha_{n+1} - n\}$ such that

$$\max\{\|Dg_{n,i+1}^n(g_{n,i+1}^j(x))\|, \|Dg_{n,i+1}^{-n}(g_{n,i+1}^{j+n}(x))\|\} > 2K_{i+1}.$$

We denote by $\varphi_{n,i+1}$ the conjugating diffeomorphism associated to the tidy perturbation $g_{n,i+1}$, which is the identity outside of $\bigcup_{j \in I_n} g_i^j(U_{i+1})$. Notice that $\varphi_{n,i+1}$ is also the identity map on $g_i^{\alpha_n}(U_{i+1})$.

We now define the diffeomorphisms g_{i+1} and φ_{i+1} that coincide respectively with g_i and id_M on $M \setminus \bigcup_{j=0}^{m_{i+1}-1} g_i^j(U_{i+1})$ and with $g_{n,i+1}$ and $\varphi_{n,i+1}$ on $\bigcup_{j \in I_n} g_i^j(U_{i+1})$, for $n \in \{n_i, \dots, n_{i+1} - 1\}$. Using the fact that the tidy perturbations $g_{n,i+1}$ have disjoint support, we obtain that g_{i+1} and φ_{i+1} have the following properties:

- g_{i+1} is a tidy perturbation of g_i with support in $\bigcup_{j=0}^{m_{i+1}-1} g_i^j(U_{i+1})$.
- g_{i+1} is conjugate to g_i by φ_{i+1} .
- φ_{i+1} is the identity map on each $g_i^{\alpha_n}(U_{i+1})$; in particular, if $x \in \Delta_{i+1}$ then $g_{i+1}^{\alpha_n}(x) \in g_i^{\alpha_n}(\Delta_{i+1})$.
- Consequently, for any $n \in \{n_{i+1}, \dots, n_{i+2} - 1\}$ and any $x \in \Delta_{i+1}$, there exists $j \in \{\alpha_n, \alpha_{n+1} - n\} \subset \{0, \dots, m_{i+1} - n\}$ such that

$$\max\{\|Dg_{i+1}^n(g_{i+1}^j(x))\|, \|Dg_{i+1}^{-n}(g_{i+1}^{j+n}(x))\|\} > 2K_{i+1}.$$

The proof of Theorem B assuming Theorem B' is now complete.

5 Large derivative by perturbation in towers

The aim of this section is to prove Theorem B', thereby completing the proof of Theorem B. In the first three subsections we reduce the problem to a linear algebra result, which is proved in the last section.

5.1 Reduction to cocycles

To any sequence (A_i) in $GL(d, \mathbb{R})$ we associate its linear cocycle as the map $f: \mathbb{Z} \times \mathbb{R}^d \rightarrow \mathbb{Z} \times \mathbb{R}^d$ defined by $(i, v) \mapsto (i+1, A_i(v))$. Theorem B' is a consequence of the following corresponding result for C^1 perturbations of linear cocycles.

Proposition 5.1. *For any $d \geq 1$ and any $C, K, \varepsilon > 0$, there exists $n_1 = n_1(d, C, K, \varepsilon) \geq 1$ with the following property.*

Consider any sequence (A_i) in $GL(d, \mathbb{R})$ with $\|A_i\|, \|A_i^{-1}\| < C$ and the associated linear cocycle f . Consider any integer $n \geq n_1$ and let $N = 2^{d+1}n$. Then for any open set $U \subset [-1, 1]^d$ and for any compact set $\Delta \subset U$, there exists a diffeomorphism g of $\mathbb{Z} \times \mathbb{R}^d$ such that:

1. *the C^1 -distance from g to f is bounded by ε ;*
2. *g is a tidy perturbation of f supported on $\bigcup_{i=0}^{N-1} f^i(\{0\} \times U)$;*
3. *for any $x \in \{0\} \times \Delta$ there exists $j \in \{0, \dots, N - n\}$ such that*

$$\max\{\|Dg^n(g^j(x))\|, \|Dg^{-n}(g^{j+n}(x))\|\} > K.$$

Proof of Theorem B' from Proposition 5.1. Fix $\tilde{\varepsilon} < \varepsilon$, let $\tilde{K} = 4K$ and set $n_0 = n_1(d, C, \tilde{K}, \tilde{\varepsilon})$, according to Proposition 5.1. Let f be a diffeomorphism of the d -manifold M with $\|Df\|, \|Df^{-1}\| < C$ and fix $n \geq n_0$. Let $N = 2^{d+1}n$. We choose $\rho_0 = \rho$ according to Lemma 3.14 associated to $\tilde{\varepsilon} < \varepsilon$ and N .

Let us show that ρ_0 satisfies the conclusions of Theorem B'. Let $U \subset M$ be an open set with diameter less than ρ_0 whose iterates $U, f(U), \dots, f^{N-1}(U)$ are pairwise disjoint, and let $\Delta \subset U$ be compact. Fix a point $x_0 \in U$.

Lemma 3.14 asserts that there are diffeomorphisms $\Psi_{f^i(x_0), i}: f^i(U) \rightarrow T_{f^i(x_0)}M$, $i \in \{0, \dots, N-1\}$ which conjugate f to its tangent map: if $y \in f^i(U)$, $i \in \{0, \dots, N-1\}$ then

$$f(y) = \Psi_{f^{i+1}(x_0), i+1}^{-1} \circ D_{f^i(x_0)}f \circ \Psi_{f^i(x_0), i}(y).$$

Moreover,

- the quantities $\|D\Psi_{f^i(x_0), i}\|$ and $\|D\Psi_{f^i(x_0), i}^{-1}\|$ are bounded by 2;
- any tidy $\tilde{\varepsilon}$ -perturbation \tilde{g} of Df with support in $\bigcup_{i=0}^{N-1} Df^i(\tilde{U})$, where $\tilde{U} = \Psi_{x_0, 0}(U)$, induces a tidy ε -perturbation g of f supported on $\bigcup_{i=0}^{N-1} f^i(U)$, through a conjugacy by the diffeomorphisms $\Psi_{f^i(x_0), i}$.

We apply Proposition 5.1 to the cocycle induced by Df on the tangent bundle $TM|_{\text{orb}(x_0)}$ over the orbit of x_0 , to the images $\tilde{U}, \tilde{\Delta}$ of U, Δ by Ψ , and to the integer n (which is larger than n_1). We obtain a (nonlinear) cocycle $\tilde{g}: \mathbb{Z} \times \mathbb{R}^d \rightarrow \mathbb{Z} \times \mathbb{R}^d$ whose C^1 -distance to Df is smaller than ε , which is a tidy perturbation of Df supported in $\bigcup_{i=0}^{N-1} Df^i(\tilde{U})$ and such that for any $x \in \tilde{\Delta}$ there exists $j \in \{0, \dots, N - n\}$ satisfying

$$\max\{\|D\tilde{g}^n(\tilde{g}^j(x))\|, \|D\tilde{g}^{-n}(\tilde{g}^{j+n}(x))\|\} > \tilde{K}. \quad (9)$$

By Lemma 3.14, the cocycle \tilde{g} defines a tidy perturbation g of f supported on $\bigcup_{i=0}^{N-1} f^i(U)$ and such that $d_{C^1}(f, g) < \varepsilon$. Consider $x \in \Delta$, $\tilde{x} = \Psi_{x_0, 0}(x) \in \tilde{\Delta}$ and the integer $j \in \{0, \dots, N - n\}$ such that (9) holds. Note that on $g^j(U)$ we have $\tilde{g}^n = \Psi_{f^{j+n}(x_0), j+n} \circ \tilde{g}^n \circ \Psi_{f^j(x_0), j}^{-1}$. Since the derivatives $\|\Psi_{f^{j+n}(x_0), j+n}\|$ and $\|\Psi_{f^j(x_0), j}^{-1}\|$ are bounded by 2, it follows that

$$\|Dg^n(g^j(x))\| \geq \frac{1}{4} \|D\tilde{g}^n(\tilde{g}^j(\tilde{x}))\|,$$

$$\|Dg^{-n}(g^{j+n}(x))\| \geq \frac{1}{4}\|D\tilde{g}^{-n}(\tilde{g}^{j+n}(\tilde{x}))\|.$$

By property (9) above, this gives

$$\max\{\|Dg^n(g^j(x))\|, \|Dg^{-n}(g^{j+n}(x))\|\} > \frac{1}{4}\tilde{K} = K.$$

□

5.2 Reduction to a perturbation result in a cube

We now reduce Proposition 5.1 to the case U is an iterate of the interior of the standard cube $Q = [-1, 1]^d$ and Δ is an iterate of a smaller closed cube δQ .

Proposition 5.2. *For any $d \geq 1$, $C, K, \varepsilon > 0$ and $\delta \in (0, 1)$, there exists an integer $n_2 = n_2(d, C, K, \varepsilon, \delta) \geq 1$ with the following property.*

Consider any sequence (A_i) in $GL(d, \mathbb{R})$ with $\|A_i\|, \|A_i^{-1}\| < C$ and the associated linear cocycle f . Then, for any $n \geq n_2$ there exists a diffeomorphism g of $\mathbb{Z} \times \mathbb{R}^d$ such that:

1. *the C^1 -distance from g to f is bounded by ε ;*
2. *g is a tidy perturbation of f supported on $\bigcup_{i=0}^{n-1} f^i(\{0\} \times Q)$;*
3. *there exists $k \in \{0, \dots, n\}$ such that for any $x \in \{0\} \times \delta Q$:*

$$\max\{\|Dg^n(g^{-k}(x))\|, \|Dg^{-n}(g^{n-k}(x))\|\} > K.$$

Remark 5.3. In Proposition 5.2, the time interval of the perturbation is $\{0, \dots, n-1\}$, and its support is $\bigcup_{i=0}^{n-1} f^i(\{0\} \times Q)$. The time $-k \in \{-n, \dots, 0\}$ where we see the large derivative property might actually lie outside of the time interval of the perturbation, and so we cannot compose two such perturbations with disjoint support without potentially destroying the large derivative property. Hence we need to consider the *effective* support of the perturbation, which is the larger set $\bigcup_{i=-n}^{n-1} f^i(\{0\} \times Q)$ corresponding to the time interval $\{-n, \dots, n-1\}$. Note that the unique value of $i \in \{-n, \dots, n-1\}$ for which we know that the intersection of the effective support of the perturbation with $\{i\} \times \mathbb{R}^d$ is a cube is $i = 0$.

Proof of Proposition 5.1, assuming Proposition 5.2. We first define the integer n_1 . Let $C, K, \varepsilon > 0$ be given. Define $K_0 = K^{2^{d+2}}$, $C_1 = C \cdot K_0^2$, $\varepsilon_2 = \frac{\varepsilon}{K_0^2}$, and $K_1 = K_0^3$. We fix $\delta = \frac{9}{10}$ and set:

$$n_1(d, C, K, \varepsilon) = n_2(d, C_1, K_1, \varepsilon_2, \delta).$$

Now consider (A_i) , N , Δ and U as in the statement of Proposition 5.1. Note that we may assume that for any $j \in \{0, \dots, N-n\}$, the product $A_{n-1+j} \cdots A_j$ and its inverse have a norm bounded by K : otherwise, the conclusion of Proposition 5.1 is satisfied for the trivial perturbation $g = f$ and this value of k .

In order to apply Proposition 5.2 we will tile the support of the perturbation. Recall our Remark 5.3 that for a perturbation supported at times $0, \dots, 2n-1$, the

tiles we use will have to be cubes “at time n ” and not “at time 0”. Thus we will tile the images $\{n\} \times \tilde{U}$ and $\{n\} \times \tilde{\Delta}$ of $\{0\} \times U$ and $\{0\} \times \Delta$ under f^n , where

$$\tilde{U} = A_{n-1} \dots A_0(U) \text{ and } \tilde{\Delta} = A_{n-1} \dots A_0(\Delta).$$

Let $a > 0$ be such that $\frac{2a}{\delta}\sqrt{d}$ is less than the distance between $\tilde{\Delta}$ and the complement of \tilde{U} . We consider a regular tiling of \mathbb{R}^d by cubes

$$\tilde{Q}_{i_1, \dots, i_d} = [-a, a]^d + (2i_1a, \dots, 2i_da), \text{ where } i_j \in \mathbb{Z}.$$

We also consider the enlarged cubes

$$Q_{i_1, \dots, i_d} = \left[-\frac{a}{\delta}, \frac{a}{\delta}\right]^d + (2i_1a, \dots, 2i_da).$$

The cubes Q_{i_1, \dots, i_d} have diameter equal to $\frac{2a}{\delta}\sqrt{d}$. By our choice of a , any cube Q_{i_1, \dots, i_d} such that $\tilde{Q}_{i_1, \dots, i_d}$ intersects the compact set Δ is entirely contained in U . We denote by Γ the family of the cubes Q_{i_1, \dots, i_d} such that $\tilde{Q}_{i_1, \dots, i_d} \cap \Delta \neq \emptyset$. Observe that two cubes Q_{i_1, \dots, i_d} and Q_{j_1, \dots, j_d} are disjoint if and only if there exists $\ell \in \{1, \dots, d\}$ with $|i_\ell - j_\ell| \geq 2$.

Now consider the families $\{\Gamma_\mu\}_{\mu \in \{0,1\}^d}$, where $\Gamma_{\mu_1, \dots, \mu_d}$ is the collection of cubes $Q_{i_1, \dots, i_d} \in \Gamma$ such that the index i_ℓ is even if $\mu_\ell = 0$ and odd if $\mu_\ell = 1$. This gives 2^d families of pairwise disjoint cubes contained in \tilde{U} such that the union of the corresponding smaller cubes $\tilde{Q}_{i_1, \dots, i_d}$ covers $\tilde{\Delta}$. To each $(\mu_1, \dots, \mu_d) \in \{0,1\}^d$ we associate the integer $\ell = \sum_{i=1}^d \mu_i 2^{i-1}$ (this formula induces a bijection from $\{0,1\}^d$ to $\{0, \dots, 2^d - 1\}$), and for simplicity we will use the notation Γ_ℓ to denote the family $\Gamma_{\mu_1, \dots, \mu_d}$. We can thus write our partition $\Gamma = \Gamma_0 \cup \dots \cup \Gamma_{2^d-1}$.

We will construct a tidy perturbation g_Q of f for each cube $Q \in \Gamma$ such that the supports of the perturbations g_Q are pairwise disjoint. The ultimate perturbation g will be obtained by combining all of these perturbations, setting g to equal g_Q on the support of g_Q and to equal f outside the union of the supports. For each cube $Q \in \Gamma_\ell$, for $\ell \in \{0, \dots, 2^d - 1\}$, the time interval of the perturbation will be $I_\ell = \{2n\ell, \dots, 2n(\ell + 1) - 1\} \subset \{0, \dots, N - 1\}$ and the support of g_Q will be

$$W_Q = \bigcup_{i \in I_\ell} f^i(\{n\} \times Q).$$

The time intervals I_ℓ form a partition of $\{0, \dots, N - 1\}$ into 2^d intervals of length $2n$, which implies that $W_Q \cap W_{Q'} = \emptyset$ for $Q \in \Gamma_\ell$, $Q' \in \Gamma_{\ell'}$ with $\ell \neq \ell'$. If $Q, Q' \in \Gamma_\ell$, then the supports are disjoint as well, because Q and Q' are disjoint.

We will now use Proposition 5.2 to construct the perturbation g_Q on W_Q . However there is an issue (as explained in Remark 5.3): the time interval I_ℓ has length $2n$, as required, but the set $f^{2n(\ell-1)}(\{n\} \times Q)$ is not (in general) a cube (unless $\ell = 0$), and so does not satisfy the hypotheses of the proposition. For this reason, for $Q \in \Gamma_\ell$ and the corresponding smaller cube $\tilde{Q} \subset Q$ we first consider

$$\widehat{W_Q} = f^{-2n\ell}(W_Q) = \bigcup_{j=0}^{2n-1} f^j(\{n\} \times Q).$$

Proposition 5.2 ensures the existence of a tidy ε_2 -perturbation $\widehat{g_Q}$ of f , supported in $\bigcup_{i=n}^{2n-1} f^i(\{n\} \times Q) \subset \widehat{W_Q}$ and of $k \in \{0, \dots, n\}$ such that for every $x \in \{n\} \times \tilde{Q}$:

$$\max\{\|D\widehat{g_Q}^n(f^{-k}(x))\|, \|D\widehat{g_Q}^{-n}(\widehat{g_Q}^n \circ f^{n-k}(x))\|\} > K_1.$$

We now define

$$g_Q = f^{2n\ell} \circ \widehat{g_Q} \circ f^{-2n\ell}.$$

Observe that:

- g_Q is a tidy perturbation of f supported in $\bigcup_{i=2n\ell+n}^{2n(\ell+1)-1} f^i(\{n\} \times Q) \subset W_Q$,
- using the bound on the products $A_{j+n-1} \dots A_j$ and the choice of ε_2 , we have:

$$d_{C^1}(g_Q, f) \leq (\max\{\|Df^n\|, \|Df^{-n}\|\})^{4\ell} d_{C^1}(\widehat{g_Q}, f) \leq K^{2^{d+2}} \varepsilon_2 \leq \varepsilon,$$

- for every $x \in \{n\} \times \tilde{Q}$:

$$\max\{\|Dg_Q^n(f^{2n\ell-k}(x))\|, \|Dg_Q^{-n}(g_Q^n \circ f^{2n\ell-k}(x))\|\} > \frac{K_1}{K^{2^{d+2}}} > K. \quad (10)$$

We finally define g by $g = g_Q$ on W_Q for $Q \in \Gamma$ and $g = f$ outside the union of the W_Q , $Q \in \Gamma$. Since the support of the tidy ε -perturbations g_Q are disjoint we get that g is a tidy ε -perturbation of f supported on $\bigcup_{i=0}^{N-1} f^i(\{0\} \times U)$, proving the two first conclusions of the proposition. Furthermore, since these perturbations are tidy, for every point $x \in \{0\} \times \mathbb{R}^d$ and every $\ell \in \mathbb{Z}$ we have $f^{2n\ell}(x) = g^{2n\ell}(x)$. What is more, since the support of the perturbation g_Q is confined to the final n iterates in the time interval I_n , we have that $f^{2n\ell+n-k}(x) = g^{2n\ell+n-k}(x)$, for any $j \in \{-n, \dots, 0\}$.

Consider now a point $x \in \{0\} \times \Delta$. We show that there exists a j such that

$$\max\{\|Dg^n(g^j(0, w))\|, \|Dg^{-n}(g^{n+j}(0, w))\|\} > K.$$

By our choice of cubes Q covering $\tilde{\Delta}$, there exists a smaller cube \tilde{Q} such that $f^n(x) \in \{n\} \times \tilde{Q}$. The corresponding cube Q belongs to some Γ_ℓ . The argument above shows that there exists $k \in \{0, \dots, -n\}$ such that (10) holds for $f^n(x)$. Using the fact that $f^{2n\ell+n-k}(x) = g^{2n\ell+n-k}(x)$, for any $k \in \{0, \dots, n\}$, we obtain that:

$$\max\{\|Dg^n(g^j(x))\|, \|Dg^{-n}(g^{n+j}(x))\|\} > K,$$

where $j = 2n\ell + n - k$. This gives the last conclusion of the proposition. \square

5.3 Reduction to linear perturbations

We first define notation and review some linear algebra. For any element $A \in GL(d, \mathbb{R})$ we define the *eccentricity* of A , denoted by $e(A)$, to be the ratio

$$\sup \left\{ \frac{\|A(u)\|}{\|A(v)\|} \text{ for } u, v \in \mathbb{R}^d, \|u\| = \|v\| = 1 \right\} = \|A\| \cdot \|A^{-1}\|.$$

Note that $e(A) \geq 1$, $e(A^{-1}) = e(A)$, and for any $B \in GL(d, \mathbb{R})$, we have $\|ABA^{-1}\| \leq e(A)\|B\|$. We will also use the conorm notation $\mathcal{M}(A) = \|A^{-1}\|^{-1}$. We recall the basic fact from linear algebra that for any $A \in GL(d, \mathbb{R})$, there exist orthogonal unit vectors u and v such that $\|Au\| = \|A\|$ and $\|Av\| = \mathcal{M}(A)$.

Proposition 5.2 is a consequence of the following proposition.

Proposition 5.4. *For any $d \geq 1$ and $C, K, \eta > 0$, there exists $n_3 = n_3(d, C, K, \eta) \geq 1$ with the following property.*

For any sequence (A_i) in $GL(d, \mathbb{R})$ satisfying $\|A_i\|, \|A_i^{-1}\| < C$ and $n \geq n_3$, there exist H_0, \dots, H_{r-1} , $0 \leq r \leq \frac{n}{2}$, in $GL(d, \mathbb{R})$ and $k \in \{0, \dots, n\}$ such that:

- *The product $P = A_{-k+n-1} \cdots A_0 H_{r-1} \cdots H_0 A_{-1} \cdots A_{-k}$ satisfies the estimate $\max\{\|P\|, \|P^{-1}\|\} > K$.*
- *For $0 \leq i < r$, the map H_i sends the standard cube Q into itself.*
- *For $0 \leq i \leq r$, there is the control*

$$(e(A_{n-i-1} \cdots A_0) + e(A_{i-1} \cdots A_0)) \cdot \|H_i - \text{id}\| < \eta.$$

We also state without proof a standard C^1 perturbation lemma.

Lemma 5.5. *For every $d \geq 1$, $\delta \in (0, 1)$ there exists a neighborhood \mathcal{O} of id in $GL(d, \mathbb{R})$ and for any $H \in \mathcal{O}$ there exists a diffeomorphism $h(H)$ of \mathbb{R}^d such that*

- *$h(H)$ coincides with the identity map on $\mathbb{R}^d \setminus Q$ and with H on δQ .*
- *The map $H \mapsto h(H)$ is C^1 in the C^1 -topology.*

Proof of Proposition 5.2 from Proposition 5.4. Lemma 5.5 associates to any H in a neighborhood \mathcal{O} of id in $GL(d, \mathbb{R})$ a diffeomorphism $h(H)$ that satisfies

$$d_{C^1}(h(H), \text{id}) \leq \theta \|H - \text{id}\|,$$

for some uniform constant $\theta > 0$. We then choose $\eta < \varepsilon/(C\theta)$ such that the ball centered at id and with radius η in $GL(d, \mathbb{R})$ is contained in \mathcal{O} . Set $n_2 = n_3(d, C, K, \eta)$.

Let (A_i) be any sequence in $GL(d, \mathbb{R})$ satisfying $\|A_i\|, \|A_i^{-1}\| < K$ and any integer $n \geq n_2$. Let us consider the sequence (H_0, \dots, H_{r-1}) and the integer $0 \leq k \leq n$ given by Proposition 5.4. By our assumptions each matrix H_i belongs to \mathcal{O} and can be associated to a diffeomorphism $h_i = h(H_i)$ by Lemma 5.5.

We define the cocycle $g : \mathbb{Z} \times \mathbb{R}^d \rightarrow \mathbb{Z} \times \mathbb{R}^d$ as follows.

$$g(x) = \begin{cases} f^{i+1} \circ h_i \circ f^{-i}(x), & \text{on } \{i\} \times \mathbb{R}^d \text{ with } 0 \leq i \leq r, \\ f^{n-i} \circ h_i^{-1} \circ f^{n-i-1}(x), & \text{on } \{n-i-1\} \times \mathbb{R}^d \text{ with } 0 \leq i \leq r, \\ f(x) & \text{otherwise.} \end{cases}$$

By construction, g is a tidy perturbation of f supported on $\bigcup_{i=0}^{n-1} f^i(\{0\} \times Q)$.

On the set $\{i\} \times \mathbb{R}^d$, for $0 \leq i \leq r$, the C^1 distance between f and g is bounded by

$$d_{C^1}(h_i, \text{id}) \leq \max\{\|A_i\|, \|A_i^{-1}\|\} \cdot e(A_{i-1} \cdots A_0) \cdot \theta \cdot \|H_i - \text{id}\| < C\theta\eta < \varepsilon.$$

The same estimate holds on $\{n - i - 1\} \times \mathbb{R}^d$. Consequently the distance $d_{C^1}(f, g)$ is bounded by ε .

Since the map h_i coincides with H_i on δQ , it maps δQ into itself. For each $0 \leq i < r$, the map g sends the set $f^i(\{0\} \times \delta Q)$ into the set $f^{i+1}(\{0\} \times \delta Q)$ and coincides with $(A_i \dots A_0)H_0(A_i \dots A_0)^{-1}$. It follows that on the set $g^{-k}(\{0\} \times \delta Q)$ the map g^n is linear and coincides with the product $P = A_{-k+n-1} \dots A_0 H_{r-1} \dots H_0 A_{-1} \dots A_{-k}$. In particular $\max\{\|Dg^n(g^{-k}(x))\|, \|Dg^{-n}(g^{n-k}(x))\|\}$ is larger than K on $\{0\} \times \delta Q$. \square

5.4 Huge versus bounded intermediary products

We now come to the proof of Proposition 5.4. Let $d \geq 1$, $K > 1$ and $C, \eta > 0$ be given. We choose $e_0 > 0$ and $s \in (0, 1)$ such that

$$e_0 > \eta^{-1}(K^2 + 1)^2 \text{ and } 2e_0 \frac{s}{1+s} < \eta.$$

Next, we choose n_3 satisfying

$$(1+s)^{n_3/2-1} > K^2.$$

Let us consider (A_i) and $n \geq n_3$ as in the statement of the proposition. We may assume that the products $A_{-k+n-1} \dots A_k$ and their inverses have a norm bounded by K , since otherwise the conclusion of Proposition 5.4 holds already. Two cases are possible.

Huge intermediary products. We first assume that

$$\text{There exists } i_0 \in \{1, \dots, n\} \text{ such that } e(A_{i_0-1} \dots A_0) > e_0.$$

Decompose the linear map $A = A_{i_0-1} A_{i_0-2} \dots A_{i_0-n}$ into a product $A = EF$, where $E = A_{i_0-1} \dots A_0$ and $F = A_{-1} \dots A_{i_0-n}$. By assumption we have $e(E) > e_0$, and $\mathcal{M}(A) = \|A^{-1}\|^{-1} \geq \frac{1}{K}$.

Let u and v be orthogonal unit vectors in \mathbb{R}^d satisfying $\|Eu\| = \|E\|$ and $\|Ev\| = \mathcal{M}(E)$. Then $\|Eu\| = e(E)\|Ev\| > e_0\|Ev\|$.

Since $e_0\eta > (K^2 + 1)^2$, we can choose $t \in \left(\frac{K^2+1}{e_0}, \frac{\eta}{K^2+1}\right)$. Let $H \in GL(d, \mathbb{R})$ be a linear map satisfying $H(v) = v + tu$ and $\|H - \text{id}\| = t$. Let $P = EHF$. We claim that the norm of P is greater than K . To show this, we will use the following elementary fact:

Claim. *Let $A, P \in GL(d, \mathbb{R})$. Suppose there exists a constant $\gamma > 0$ and a nonzero vector $w \in \mathbb{R}^d$ such that $\|Pw\| > \gamma\|Aw\|$. Then $\|P\| > \gamma\mathcal{M}(A)$.*

To apply this lemma, we set $w = F^{-1}(v)$, and calculate:

$$\begin{aligned} \|Pw\| &= \|EHF(F^{-1}(v))\| = \|EH(v)\| = \|E(v + tu)\| \geq t\|E(u)\| - \|E(v)\| \\ &> (te_0 - 1)\|E(v)\| = (te_0 - 1)\|Aw\|. \end{aligned}$$

Applying the lemma with $\gamma = te_0 - 1$, we see that

$$\|P\| > (te_0 - 1)\mathcal{M}(A) \geq \frac{(te_0 - 1)}{K} > K,$$

by our lower bound on t .

By setting $r = 0$ and $H_0 = H$, we obtain the first conclusion of the proposition. The second one is empty. Since $\|A_{n-1} \dots A_0\|$ and $\|(A_{n-1} \dots A_0)^{-1}\|$ are bounded by K , we obtain that $e(A_{n-1} \dots A_0) < K^2$. As a consequence, we have

$$(e(A_{n-1} \dots A_0) + 1)\|H_0 - \text{id}\| \leq (K^2 + 1)t < \eta,$$

by our upper bound on t . This gives the last conclusion.

Bounded intermediary products. Assume, on the other hand, that

$$\text{For any } i_0 \in \{1, \dots, n\} \text{ we have } e(A_{i_0-1} \dots A_0) \leq e_0.$$

Let $r = \lfloor \frac{n}{2} \rfloor$ and let $H \in GL(d, \mathbb{R})$ be the linear conformal dilation $H = (1 + s)^{-1}I$. Since this is a linear contraction, H maps the standard cube Q into itself. We define $H_i = H$ for any $i = 0, \dots, r-1$. Note that

$$(e(A_{n-i-1} \dots A_0) + e(A_{i-1} \dots A_0)) \cdot \|H_i - \text{id}\| \leq 2e_0 \frac{s}{1+s} < \eta,$$

by our choice of s .

It is straightforward to check that for $k = n - r$, the product $P = A_{-k+n-1} \dots A_0 H_{r-1} \dots H_0 A_{-1} \dots A_{-k}$ satisfies

$$\|P^{-1}\| \geq (1+s)^r \|A_{-k+n-1} \dots A_{-k}\| > (1+s)^{n_3/2-1} K^{-1} > K,$$

by our choice of n_3 . The conclusions of the proposition are thus satisfied.

6 (UD) property: reduction to a perturbation result in a cube

The aim of this section is to provide successive reductions for Theorem A. At the end we are led to a perturbation result (Proposition 6.6) for cocycles that produces an arbitrarily large variation of the jacobian along orbits in a cube. Many of the difficulties we meet in the proof of Theorem A come from the fact that we have not been able to create a large change in the jacobian of a linear cocycle, inside a cube, by a tidy perturbation.

6.1 Reduction to a perturbation result in towers

We show that Theorem B follows from a perturbation result that produces arbitrarily large distortion between a given orbit and the orbit of a wandering compact set.

Proposition 6.1. *Consider a diffeomorphism f , a compact ball Δ , an open set U , and a point x of M satisfying:*

- $f(\overline{U}) \subset U$;
- $\Delta \subset U \setminus f(\overline{U})$;
- the orbit of x is disjoint from Δ .

Then for any $K, \varepsilon > 0$ there exists a diffeomorphism g with $d_{C^1}(f, g) < \varepsilon$ having the following property: for all $y \in \Delta$, there exists $n \geq 1$ such that

$$|\log \det Dg^n(x) - \log \det Dg^n(y)| > K.$$

Moreover, $f = g$ on a neighborhood of the chain-recurrent set $CR(f)$.

Proof of Theorem A from Proposition 6.1. Let $\mathcal{X} \subset M$ be a countable dense set and let $\mathcal{K} = \{\Delta_n\}$ be a countable collection of compact balls in M satisfying:

- $\text{diam} \Delta_n \rightarrow 0$ as $n \rightarrow \infty$, and
- $\bigcup_{n \geq n_1} \Delta_n = M$ for all $n_1 \geq 1$.

For $\Delta \in \mathcal{K}$, define the open subset of $\text{Diff}^1(M)$:

$$\mathcal{O}_\Delta = \{f \in \text{Diff}^1(M) \mid \exists \text{ open set } U, f(\overline{U}) \subset U, \Delta \subset U \setminus f(\overline{U})\}.$$

For $x \in \mathcal{X}$, define

$$\mathcal{U}_{x,\Delta} = \{f \in \mathcal{O}_\Delta \mid \text{orb}_f(x) \cap \Delta = \emptyset\}.$$

Notice that $f \in \mathcal{U}_{x,\Delta}$ means that there is an open set U such that (Δ, U, x) satisfies the hypotheses of Proposition 6.1.

The set $\mathcal{U}_{x,\Delta}$ is not open. The next lemma gives a simple criterion for f to belong to its interior:

Lemma 6.2. *Consider $f \in \mathcal{U}_{x,\Delta}$ and an open subset U of M with $f(\overline{U}) \subset U$, $\Delta \subset U \setminus f(\overline{U})$. Assume that the orbit of x meets $U \setminus f(\overline{U})$. Then f belongs to the interior of $\mathcal{U}_{x,\Delta}$: the orbit of x under any diffeomorphism g sufficiently C^1 -close to f is disjoint from Δ .*

Proof. Consider $i \in \mathbb{Z}$ such $f^i(x) \in U \setminus \overline{f(U)}$. Such a number i is unique, because $U \setminus \overline{f(U)}$ is the fundamental domain of an attracting region U and hence is disjoint from all its iterates. Moreover, there is a neighborhood \mathcal{U} of f such that every $g \in \mathcal{U}$ satisfies:

- $g(\overline{U}) \subset U$,
- $\Delta \subset U \setminus \overline{g(U)}$,
- $g^i(x) \in U \setminus (\overline{g(U)} \cup \Delta)$.

This shows that the open neighborhood \mathcal{U} of f is contained in $\mathcal{U}_{x,\Delta}$. □

In order to obtain a residual set, we must first produce a countable family of open and dense subsets of $\text{Diff}^1(M)$. However the sets $\mathcal{U}_{x,\Delta}$ are neither open nor closed. The next lemma shows the way to bypass this difficulty:

Lemma 6.3. *The set $\text{Int}(\mathcal{U}_{x,\Delta}) \cup \text{Int}(\mathcal{O}_\Delta \setminus \mathcal{U}_{x,\Delta})$ is open and dense in \mathcal{O}_Δ .*

Proof. The set $\text{Int}(\mathcal{U}_{x,\Delta}) \cup \text{Int}(\mathcal{O}_\Delta \setminus \mathcal{U}_{x,\Delta})$ is open by definition; we just have to prove its density in \mathcal{O}_Δ .

Fix $f \in \mathcal{O}_\Delta$. Then there exists an open set $U \subset M$ and an open neighborhood $\mathcal{U} \subset \mathcal{O}_\Delta$ of f such that for $g \in \mathcal{U}$ we have $g(\overline{U}) \subset U$ and $\Delta \subset U \setminus g(\overline{U})$. Now fix $x \in X$. We will show that $\mathcal{U} \cap (\text{Int}(\mathcal{U}_{x,\Delta}) \cup \text{Int}(\mathcal{O}_\Delta \setminus \mathcal{U}_{x,\Delta}))$ is dense in \mathcal{U} .

Let $\mathcal{V} \subset \mathcal{U}$ be the open subset of diffeomorphisms g such that the orbit $\text{orb}_g(x)$ meets $U \setminus g(\overline{U})$. Any diffeomorphism $g \in \mathcal{U} \setminus \mathcal{V}$ belongs to $\mathcal{U}_{x,\Delta}$: the orbit of x is disjoint from $U \setminus g(\overline{U})$, and so is disjoint *a fortiori* from Δ . Let $\mathcal{W}_0 = \mathcal{U} \setminus \mathcal{V}$. By construction, $\mathcal{V} \cup \mathcal{W}_0$ is open and dense in \mathcal{U} , and $\mathcal{W}_0 \subset \text{Int}(\mathcal{U}_{x,\Delta})$.

Lemma 6.2 asserts that $\mathcal{V}_0 = \mathcal{V} \cap U_{x,\Delta}$ is open. Let $\mathcal{W}_1 = \mathcal{V} \setminus \mathcal{V}_0$. Then \mathcal{W}_1 is an open set contained in $\mathcal{O}_\Delta \setminus \mathcal{U}_{x,\Delta}$ and hence in $\text{Int}(\mathcal{O}_\Delta \setminus \mathcal{U}_{x,\Delta})$. Moreover, $\mathcal{V}_0 \cup \mathcal{W}_1$ is open and dense in \mathcal{V} . We have thus shown that $\mathcal{V}_0 \cup \mathcal{W}_1 \cup \mathcal{W}_0$ is an open and dense subset of \mathcal{U} contained in $\text{Int}(\mathcal{U}_{x,\Delta}) \cup \text{Int}(\mathcal{O}_\Delta \setminus \mathcal{U}_{x,\Delta})$, ending the proof. \square

For $x \in \mathcal{X}$, $\Delta \in \mathcal{K}$ and any integer $K \in \mathbb{N}$, we define:

$$\mathcal{V}_{x,\Delta,K} = \{f \in \text{Int}(\mathcal{U}_{x,\Delta}) \mid \forall y \in \Delta, \exists n \geq 1, \\ |\log \det Df^n(x) - \log \det Df^n(y)| > K\}.$$

Note that $\mathcal{V}_{x,\Delta,K}$ is open in $\text{Int}(\mathcal{U}_{x,\Delta})$. Furthermore $\mathcal{V}_{x,\Delta,K}$ is dense in $\text{Int}(\mathcal{U}_{x,\Delta})$, by Proposition 6.1. It follows that the set

$$\mathcal{W}_{x,\Delta,K} = \mathcal{V}_{x,\Delta,K} \cup \text{Int}(\mathcal{O}_\Delta \setminus \mathcal{U}_{x,\Delta}) \cup \text{Int}(\text{Diff}^1(M) \setminus \mathcal{O}_\Delta)$$

is open and dense in $\text{Diff}^1(M)$. Next, we set

$$\mathcal{G}_0 = \bigcap \mathcal{W}_{x,\Delta,K},$$

where the intersection is taken over $x \in \mathcal{X}$, $\Delta \in \mathcal{K}$, and $K \in \mathbb{N}$. This set is residual in $\text{Diff}^1(M)$. Finally, we take \mathcal{G} to be the intersection of \mathcal{G}_0 with the residual set of $f \in \text{Diff}^1(M)$ constructed in [BC] where the chain recurrent and nonwandering sets coincide.

Consider $f \in \mathcal{G}$. Fix $x \in \mathcal{X}$ and $y \in M \setminus \Omega(f) = M \setminus CR(f)$ such that $\text{orb}(x) \cap \text{orb}(y) = \emptyset$. Since y is not chain recurrent, Conley theory implies that there exists an open set $U \subset M$ such that $f(\overline{U}) \subset U$ and $y \in U \setminus \overline{f(U)}$ (see Section 2.1). Observe that $\text{orb}(x) \cap U \setminus \overline{f(U)}$ contains at most one point; it is distinct from y by assumption. Thus any compact set $\Delta \in \mathcal{K}$ containing y and with sufficiently small diameter satisfies

- $\Delta \subset U \setminus \overline{f(U)}$,
- $\text{orb}(x) \cap \Delta = \emptyset$.

We fix such a compact set $\Delta \in \mathcal{K}$. This implies that $f \in \mathcal{U}_{x,\Delta}$. Since $f \in \mathcal{G}_0$, the definition of \mathcal{G}_0 implies that for every $K \in \mathbb{N}$, we have $f \in \mathcal{W}_{x,\Delta,K}$; since $f \in \mathcal{U}_{x,\Delta}$, we must have $f \in \mathcal{V}_{x,\Delta,K}$. This means that, for every K , we have for some $n \geq 1$

$$|\log \det Df^n(x) - \log \det Df^n(y)| > K.$$

Hence f satisfies property (UD) on the nonwandering set. \square

6.2 Localization of the perturbation

Here we reduce Proposition 6.1 to the case where Δ has small diameter.

We use the following notation. If $X \subset M$ is a compact set and $\delta > 0$ then $U_\delta(X)$ denotes the δ -neighborhood of X : $U_\delta(X) = \{y \in M \mid d(y, X) < \delta\}$.

Proposition 6.4. *For any $d \geq 1$ and $C, K, \varepsilon > 0$, there exists $n_0 = n_0(C, K, \varepsilon)$ with the following property.*

For any diffeomorphism f of a d -dimensional manifold M satisfying $\|Df\|, \|Df^{-1}\| < C$, there exists $\rho_0 = \rho_0(d, C, K, \varepsilon)$ such that for any $\eta > 0$, any compact set $\Delta \subset M$ and $x \in M$ satisfying:

- $\text{diam}(\Delta) < \rho_0$,
- Δ is disjoint from its first n_0 iterates $\{f^i(\Delta) : 1 \leq i \leq n_0\}$,
- $\text{orb}(x) \cap \Delta = \emptyset$,

there exists a diffeomorphism $g \in \text{Diff}^1(M)$ such that

- $d_{C^1}(f, g) < \varepsilon$,
- $d_{C^0}(f, g) < \eta$,
- *for all $y \in \Delta$, there exists an integer $n \in \{1, \dots, n_0\}$ such that:*

$$|\log \det Dg^n(x) - \log \det Dg^n(y)| > K.$$

Moreover, $f = g$ on the complement of $U_\eta(\bigcup_{i=0}^{n_0-1} f^i(\Delta))$.

Proof of Proposition 6.1 from Proposition 6.4. Let f, Δ, U, x be as in the statement of Proposition 6.1. Choose $n_0 = n_0(d, C, 2K, \varepsilon)$ and $\rho_0 = \rho_0(d, C, K, \varepsilon)$ according to Proposition 6.4. We set $N = 2^d n_0$.

Cover Δ by a finite collection \mathcal{F} of compact sets satisfying:

- $\Delta \subset \bigcup_{D \in \mathcal{F}} \text{Int}(D) \subset U \setminus f(\overline{U})$, so that for each $D \in \mathcal{F}$ the iterates $D, f(D), f^2(D), \dots$ are pairwise disjoint;
- $\text{orb}(x) \cap \bigcup_{D \in \mathcal{F}} D = \emptyset$;
- $\text{diam}(f^i(D)) < \rho_0$, for all $D \in \mathcal{F}$ and $i \in \{0, \dots, N\}$;
- $\mathcal{F} = \mathcal{F}_0 \cup \dots \cup \mathcal{F}_{2^d-1}$, where $\mathcal{F}_i \cap \mathcal{F}_j = \emptyset$ for $i \neq j$ and the elements of \mathcal{F}_j are pairwise disjoint for each j .

One can obtain \mathcal{F} by tiling by arbitrarily small cubes the compact ball Δ .

Let $\lambda > 0$ be the Lebesgue number of the cover \mathcal{F} . For any $\eta > 0$ we define an increasing sequence $(a_\eta(n))$ by the inductive formula:

$$a_\eta(0) = 0; \quad a_\eta(n+1) = C a_\eta(n) + \eta.$$

Note that for $n \geq 0$ fixed, we have $a_\eta(n) \rightarrow 0$ as $\eta \rightarrow 0$.

Let $\eta > 0$ be small such that:

- for each $D \in \mathcal{F}$ and $0 \leq i < N-1$, the η -neighborhood $U_\eta(f^i(D))$ is contained in $f^i(U) \setminus \overline{f^{i+1}(U)}$; in particular the sets $U_\eta(D), \dots, U_\eta(f^{N-1}(D))$ are pairwise disjoint;
- the orbit $\text{orb}(x)$ is disjoint from the union $\bigcup_{i \in \{0, \dots, N\}} U_\eta(f^i(D))$;
- for each distinct (j, D) and (j', D') with $j, j' \in \{0, \dots, 2^d - 1\}$ and $D \in \mathcal{F}_j$, $D' \in \mathcal{F}_{j'}$, we have for all $k, k' \in \{0, \dots, n_0 - 1\}$,

$$U_\eta(f^{n_0j+k}(D)) \cap U_\eta(f^{n_0j'+k'}(D')) = \emptyset;$$

- $a_\eta(N) < C^{-N}\lambda$.

For $j \in \{0, \dots, 2^d - 1\}$ and $D \in \mathcal{F}_j$, the set $f^{n_0j}(D)$ and the point $f^{n_0j}(x)$ satisfy the hypotheses of Proposition 6.4. We obtain a perturbation of f supported on the η -neighborhood of $\bigcup_{k \in \{0, \dots, n_0-1\}} f^{n_0j+k}(D)$; by our choice of η , any two such perturbations for distinct choices of (j, D) will be disjointly supported. Hence, applying Proposition 6.4 over all pairs (j, D) with $j \in \{0, \dots, 2^d - 1\}$ and $D \in \mathcal{F}_j$, we obtain a perturbation g with the following properties:

1. $d_{C^1}(f, g) < \varepsilon$;
2. $d_{C^0}(f, g) < \eta$;
3. $g = f$ on $M \setminus U_\eta\left(\bigcup_{k=0}^{N-1} f^k(D)\right)$;
4. for each $j \in \{0, \dots, 2^d - 1\}$ and each $y \in \bigcup_{D \in \mathcal{F}_j} D$, there exists $n \in \{1, \dots, n_0\}$ such that:

$$\left| \log \det Dg^n(f^{n_0j}x) - \log \det Dg^n(f^{n_0j}y) \right| > 2K. \quad (11)$$

We now prove the large derivative formula. We fix $y \in \Delta$.

Claim. *There exist $j \in \{0, \dots, 2^d - 1\}$ and $D \in \mathcal{F}_j$ such that $g^{n_0j}(y) \in f^{n_0j}(D)$.*

Proof. Choose $D \in \mathcal{F}$ such that the ball $B(y, \lambda)$ is contained in D and fix $j \in \{1, \dots, 2^d\}$ such that $D \in \mathcal{F}_j$. This implies that $B(f^k(y), C^{-k}\lambda) \subset f^k(D)$, for all $k \in \{0, \dots, N-1\}$. Note that

$$\begin{aligned} d(f^{k+1}(y), g^{k+1}(y)) &\leq d(f^{k+1}(y), f(g^k(y))) + d(f(g^k(y)), g^{k+1}(y)) \\ &\leq Cd(f^k(y), g^k(y)) + \eta, \end{aligned}$$

which implies, by Property 2 above and our choice of λ , that for any $k \in \{0, \dots, N-1\}$ we have:

$$d(f^k(y), g^k(y)) \leq a_\eta(k) < C^{-N}\lambda.$$

We conclude that $g^{n_0j}(y) \in f^{n_0j}(D)$. □

Since the orbit of x is disjoint from the support of the perturbation, we have that $f^{n_0j}(x) = g^{n_0j}(x)$, for all $j \in \{1, \dots, 2^d - 1\}$. From these properties and from (11), there exist $j \in \{0, \dots, 2^d - 1\}$ and $n \in \{1, \dots, n_0\}$ such that:

$$\left| \log \det Dg^n(g^{n_0j}x) - \log \det Dg^n(g^{n_0j}y) \right| > 2K.$$

The fact that $Dg^{n+n_0j} = Dg^n \circ Dg^{n_0j}$ implies that one of these two cases holds:

- either $|\log \det Dg^{n_0j}(x) - \log \det Dg^{n_0j}(y)| > K$,
- or $|\log \det Dg^{n+n_0j}(x) - \log \det Dg^{n+n_0j}(y)| > K$.

In any case, there exists $n \in \{1, \dots, N\}$ such that the required estimate $|\log \det Dg^n(x) - \log \det Dg^n(y)| > K$ holds.

By construction the support of the perturbation is contained in a finite number of iterates of $U \setminus \overline{f(U)}$; the iterates of $U \setminus \overline{f(U)}$ for f and g hence coincide. This implies that $CR(f) = CR(g)$. \square

6.3 Reduction to cocycles

Proposition 6.4 is a consequence of the following result about cocycles.

Proposition 6.5. *For any $d \geq 1$ and any $C, K, \varepsilon > 0$, there exists $n_1 = n_1(d, C, K, \varepsilon) \geq 1$ with the following property.*

Consider any sequence (A_i) in $GL(d, \mathbb{R})$ with $\|A_i\|, \|A_i^{-1}\| < C$ and the associated cocycle f . Then, for any open set $U \subset \mathbb{R}^d$, for any compact set $\Delta \subset U$ and for any $\eta > 0$, there exists a diffeomorphism g of $\mathbb{Z} \times \mathbb{R}^d$ such that:

- $d_{C^1}(f, g) < \varepsilon$,
- $d_{C^0}(f, g) < \eta$,
- $g = f$ on the complement of $\bigcup_{i=0}^{2n_1-1} f^i(\{0\} \times U)$,
- for all $y \in \{0\} \times \Delta$, there exists $n \in \{1, \dots, n_1\}$ such that

$$|\log \det Df^n(y) - \log \det Dg^n(y)| > K.$$

Proof of Proposition 6.4 from Proposition 6.5. Fix $d, C, K, \varepsilon > 0$, choose $0 < \tilde{\varepsilon} < \varepsilon$, $K_0 > 2K + 8 \log 2$ and set $n_0 = 2n_1(d, C, K_0, \tilde{\varepsilon})$.

Let $f: M \rightarrow M$ be a diffeomorphism such that $\|Df\|, \|Df^{-1}\| < C$ and let $\delta > 0$ be the constant associated to f , $\tilde{\varepsilon}$, ε , and n_0 by Lemma 3.14. Fix $\rho_0 \in (0, \frac{\delta}{2}C^{-n_1})$.

Consider η , Δ and x as in the statement of Proposition 6.4. We fix an open neighborhood U of Δ such that:

- $\text{diam}(U) < \rho_0$; in particular $\text{diam}(f^i(U)) < \delta$ for all $i \in \{0, \dots, n_1\}$;
- U is disjoint from its first n_0 iterates;
- $f^i(x) \notin U$ for $i \in \{0, \dots, n_0\}$.

Fix a point $z_0 \in \Delta$ and let \tilde{f} denote the linear cocycle induced by the derivative Df along the orbit of z_0 .

By Lemma 3.14, there are diffeomorphisms $\Psi_i: f^i(U) \rightarrow \tilde{U}_i \subset T_{f^i(z_0)}M$ for $i \in \{0, \dots, n_1\}$, which conjugate f to \tilde{f} : for every $z \in f^i(U)$ we have $\tilde{f}(\Psi_i(z)) = \Psi_{i+1}(f(z))$. Moreover,

- $\|D\Psi_i\|$, $\|D\Psi_i^{-1}\|$, $|\det D\Psi_i|$ and $|\det D\Psi_i^{-1}|$ are bounded by 2;
- any $\tilde{\varepsilon}$ -perturbation \tilde{g} of \tilde{f} with support in $\bigcup_{i=0}^{n_0-1} \tilde{U}_i$ induces a diffeomorphism g which is a ε -perturbation of f supported on $\bigcup_{i=0}^{n_0-1} f^i(U)$ through a conjugacy by the diffeomorphisms Ψ_i .

We denote by $\Psi: \bigcup_{i=0}^{n_0} f^i(U) \rightarrow \bigcup_{i=0}^{n_0} \tilde{U}_i$ the diffeomorphism that is equal to Ψ_i on $f^i(U)$.

We now apply Proposition 6.5 to obtain a $\tilde{\varepsilon}$ -perturbation \tilde{g} of \tilde{f} supported in $\bigcup_{i=0}^{n_0-1} \tilde{U}_i$ such that for every $y \in \Psi_0(\Delta)$ we have:

- $d_{C^0}(\tilde{f}, \tilde{g}) < \frac{\eta}{2}$,
- $\tilde{g} = \tilde{f}$ on the complement of $\bigcup_{i=0}^{n_0-1} \tilde{U}_i$,
- for all $y \in \Psi_0(\Delta)$ there exists $n \in \{1, \dots, n_0\}$ such that

$$\left| \log \det D\tilde{f}^n(y) - \log \det D\tilde{g}^n(y) \right| > K_0.$$

Let g be the corresponding ε -perturbation of f . Since Ψ satisfies $\|D\Psi^{-1}\| \leq 2$, we obtain that

$$d_{C^0}(f, g) < 2d_{C^0}(\tilde{f}, \tilde{g}) < \eta.$$

Furthermore, for each $z \in \Delta$, there exists $n \in \{1, \dots, n_0\}$ such that

$$|\log \det Df^n(z) - \log \det Dg^n(z)| > K_0 - 4 \log 2. \quad (12)$$

For $n \in \{0, \dots, n_0 - 1\}$, the maps f^n and $Df^n(z_0)$ are conjugate on Δ by the diffeomorphism Ψ . Since $\|\det D\Psi\| \in [\frac{1}{2}, 2]$, this implies that, for every $z \in \Delta$, we have $|\log \det Df^n(z_0) - \log \det Df^n(z)| \leq 2 \log 2$. If there exists $n \in \{0, \dots, n_0 - 1\}$ such that $|\log \det Df^n(z_0) - \log \det Df^n(x)| > K + 2 \log 2$, then we do not perturb f : in this case, every point $z \in \Delta$ satisfies $|\log \det Df^n(z) - \log \det Df^n(x)| > K$ as required. Hence we may assume that for every $n \in \{0, \dots, n_0 - 1\}$ and every $z \in \Delta$ we have

$$|\log \det Df^n(z) - \log \det Df^n(x)| \leq K + 2 \log 2. \quad (13)$$

Notice that the support of the perturbation g is disjoint from the set $\{x, f(x), \dots, f^{n_0}(x)\}$, so that $Df^n(x) = Dg^n(x)$ for $n \in \{0, \dots, n_0\}$. Inequality (12) implies that for every $z \in \Delta$ there exists $n \in \{1, \dots, n_0\}$ such that

$$\begin{aligned} \left| \log \frac{\det Dg^n(x)}{\det Dg^n(z)} \right| &> \left| \log \frac{\det Df^n(z)}{\det Dg^n(z)} \right| - \left| \log \frac{\det Df^n(x)}{\det Df^n(z)} \right| \\ &> K_0 - 4 \log 2 - K - 4 \log 2 > K. \end{aligned}$$

This completes the proof of Proposition 6.4, assuming Proposition 6.5. \square

6.4 Reduction to a perturbation result in a cube

We now reduce Proposition 6.5 to the case where U is the interior of a cube Q_μ , which has to be chosen to be very thin along one coordinate, and Δ is a smaller cube θQ_μ .

We thus consider the space \mathbb{R}^d as a product $\mathbb{R}^{d-1} \times \mathbb{R}$ and denote by (v, z) its coordinates. For a constant $\mu > 0$, let E_μ be the linear isomorphism of \mathbb{R}^d defined by $E_\mu(v, z) = (v, \mu z)$. The image of the standard cube $Q = [-1, 1]^d$ by E_μ will be denoted by $Q_\mu = [-1, 1]^{d-1} \times [-\mu, \mu]$.

Proposition 6.6. *For any $d \geq 1$, $C, K, \varepsilon > 0$ and $\theta \in (0, 1)$, there exists $n_2 = n_2(d, C, K, \varepsilon, \theta) \geq 1$ and for any $\eta > 0$ there exists $\mu_0 = \mu_0(d, C, K, \varepsilon, \theta, \eta) > 0$ with the following property.*

Consider any sequence (A_i) in $GL(d, \mathbb{R})$ with $\|A_i\|, \|A_i^{-1}\| < C$ and the associated linear cocycle f . Consider any $\mu \in (0, \mu_0)$ and $j \in \{0, \dots, 2^d - 1\}$. Then there exists a diffeomorphism g of $\mathbb{Z} \times \mathbb{R}^d$ such that:

- $d_{C^1}(f, g) < \varepsilon$;
- $g = f$ on the complement of $\bigcup_{i=2jn_2}^{2(j+1)n_2-1} f^i(\{0\} \times Q_\mu)$;
- for all $x \in \{0\} \times \theta Q_\mu$,

$$\left| \log \det Df^{n_2}(f^{2jn_2}(x)) - \log \det Dg^{n_2}(f^{2jn_2}(x)) \right| > K;$$

- on $\{0\} \times \mathbb{R}^d$, we have:

$$d_{\text{unif}}(\text{id}, E_\mu^{-1} f^{-2(j+1)n_2} g^{2(j+1)n_2} E_\mu|_{\{0\} \times \mathbb{R}^d}) < \eta.$$

Proof of Proposition 6.5 from Proposition 6.6. The proof is partly similar to the proof of Proposition 5.1. Let $C, K, \varepsilon > 0$ be given. We fix $\theta = \frac{9}{10}$ and set

$$n_1(d, C, K, \varepsilon) = 2^{d+1} n_2(C, 2K, \varepsilon, \theta) \geq 1.$$

Consider (A_i) , Δ , U , η as in the statement of Proposition 6.5. Up to rescaling by homothety, we may assume that:

$$C^{2^{d+1}n_1} 2\theta^{-1} \sqrt{d} < d(\Delta, \mathbb{R}^d \setminus U), \quad (14)$$

$$C^{2^{d+1}n_1} 2\theta^{-1} \sqrt{d} < \eta. \quad (15)$$

Indeed let us consider some $a \in (0, 1)$ and the homothety $h_{\frac{1}{a}}$ of \mathbb{R}^d with ratio $\frac{1}{a}$. If g_0 is a perturbation of f satisfying the conclusions of Proposition 6.5 for C, K, ε , $h_{\frac{1}{a}}(\Delta)$, $h_{\frac{1}{a}}(U)$ and $\frac{\eta}{a}$, then $g = h_a g_0 h_{\frac{1}{a}}$ is a perturbation of f satisfying the conclusions of Proposition 6.5 for C, K, ε , Δ , U and η . Hence we may assume that the estimates (14) and (15) hold by choosing a small enough.

In order to apply Proposition 6.6, we tile the set U . The tiling we use has the same structure as the tiling used in Proposition 5.1, producing 2^d disjoint families

Figure 1: Tiling of the plane used in (LD) perturbation theorem (left) and (UD) perturbation theorem (right). The different shadings correspond to the partition into $2^d = 4$ families.

of tiles, but the geometry is different (see Figure 1). We first consider the regular tilings \mathcal{T} and $\tilde{\mathcal{T}}$ of \mathbb{R}^d by the cubes

$$Q_{i_1, \dots, i_d} = [-\theta^{-1}, \theta^{-1}]^d + (i_1, \dots, i_d),$$

$$\tilde{Q}_{i_1, \dots, i_d} = [-\theta^{-2}, \theta^{-2}]^d + (i_1, \dots, i_d),$$

respectively, where $(i_1, \dots, i_d) \in \mathbb{Z}^d$. Let λ be the Lebesgue number of the cover \mathcal{T} of \mathbb{R}^d . We choose $\eta_0 > 0$ smaller than $2^{-d}\lambda$.

Now fix $\mu \in (0, 1)$ smaller than $\mu_0(C, 2K, \varepsilon, \theta, \eta_0)$ and denote by \mathcal{T}_μ and $\tilde{\mathcal{T}}_\mu$ the images of the tilings \mathcal{T} and $\tilde{\mathcal{T}}$ by E_μ . These are the tilings of \mathbb{R}^d by the cubes

$$Q_{\mu, (i_1, \dots, i_d)} = [-\theta^{-1}, \theta^{-1}]^{d-1} \times [-\theta^{-1}\mu, \theta^{-1}\mu] + (i_1, \dots, i_{d-1}, \mu i_d),$$

$$\tilde{Q}_{\mu, (i_1, \dots, i_d)} = [-\theta^{-2}, \theta^{-2}]^{d-1} \times [-\theta^{-2}\mu, \theta^{-2}\mu] + (i_1, \dots, i_{d-1}, \mu i_d),$$

respectively. By our assumption (14), any cube $Q_{\mu, (i_1, \dots, i_d)}$ such that $\tilde{Q}_{\mu, (i_1, \dots, i_d)}$ intersects the compact set Δ is contained in U . We denote by Γ_μ the family of cubes $Q_{\mu, (i_1, \dots, i_d)}$ such that $\tilde{Q}_{\mu, (i_1, \dots, i_d)}$ intersects Δ .

We next consider the partition $\Gamma_\mu = \bigcup_{\ell=0}^{2^d-1} \Gamma_{\mu, \ell}$ such that for pair of any elements Q, Q' in $\Gamma_{\mu, \ell}$, the enlarged cubes \tilde{Q}, \tilde{Q}' are disjoint. (As in Section 5.2 we set $Q_{\mu, (i_1, \dots, i_d)} \in \Gamma_{\mu, \ell}$ if $\ell = \sum_{j=1}^d \alpha_j 2^{j-1}$ where $\alpha_j = 0$ if i_j is even and $\alpha_j = 1$ if i_j is odd).

For each cube $Q \in \Gamma_{\mu, \ell}$, we also introduce the time interval $I_\ell = \{2n_2\ell, \dots, 2n_2(\ell+1) - 1\}$. Proposition 6.6 produces a perturbation g_Q supported on the union

$$W_Q = \bigcup_{i \in I_\ell} f^i(\{0\} \times \tilde{Q}).$$

The construction of the families $\Gamma_{\mu, \ell}$ and of the intervals I_ℓ implies that W_Q and $W_{Q'}$ are disjoint if $Q, Q' \in \Gamma_\mu$ are distinct. We finally define g by g_Q on W_Q , for $Q \in \Gamma_{\mu, \ell}$, and $g = f$ elsewhere. In particular, we have $g = f$ on the complement of $\bigcup_{i=0}^{n_1-1} f^i(\{0\} \times U)$. The perturbation g is supported in a disjoint union of images

$f^i(\{0\} \times \tilde{Q}_{\mu, (i_1, \dots, i_d)})$ for $i \in \{0, \dots, 2^d n_1 - 1\}$ and by (15) satisfies $d_{C^0}(f, g) < \eta$. Each perturbation g_Q satisfies $d_{C^1}(g_Q, f) < \varepsilon$, and hence $d_{C^1}(g, f) < \varepsilon$ holds. It remains to prove the last part of the conclusion of the proposition.

Claim. *For every $y \in \{0\} \times \Delta$, there exist $\ell \in \{0, \dots, 2^d - 1\}$ and $Q \in \Gamma_\ell$ such that $g_\eta^{2n_2\ell}(y) \in f^{2n_2\ell}(Q)$.*

Proof. By definition of λ , the ball $B(E_\mu^{-1}(y), \lambda)$ is contained in some cube $Q_{(i_1, \dots, i_d)}$. The cube $Q = Q_{\mu, (i_1, \dots, i_d)} = E_\mu(Q_{(i_1, \dots, i_d)})$ contains $y \in \Delta$ and hence belongs to $\Gamma_{\mu, \ell}$. Let $\ell \in \{0, \dots, 2^d - 1\}$ be such that $Q_{\mu, (i_1, \dots, i_d)} \in \Gamma_{\mu, \ell}$.

Since $d_{unif}(\text{id}, E_\mu^{-1} f^{-2n_2(j+1)} g_Q^{2n_2} f^{2n_2(j)} E_\mu) < \eta_0$ for each $j \in \{0, \dots, 2^d - 1\}$, we obtain the bound

$$\begin{aligned} d_{unif}(\text{id}, E_\mu^{-1} f^{-2n_2\ell} g^{2n_2\ell} E_\mu) &\leq \sum_{j=0}^{\ell-1} d_{unif}(\text{id}, E_\mu^{-1} f^{-2n_2(j+1)} g^{2n_2} f^{2n_2(j)} E_\mu) \\ &< 2^\ell \eta_0 \leq 2^d \eta_0 < \lambda, \end{aligned}$$

by our choice of η_0 .

By our estimate above, the point $E_\mu^{-1} f^{-2n_2\ell} g^{2n_2\ell} E_\mu(E_\mu^{-1}(y))$ belongs to the ball $B(E_\mu^{-1}(y), \lambda)$ and hence to $Q_{(i_1, \dots, i_d)}$. This proves that $f^{2n_2\ell}(Q)$ contains the point $g^{2n_2\ell}(y)$ as required. \square

In order to conclude, we fix a point $y \in \{0\} \times \Delta$ and $\ell \in \{0, \dots, 2^d - 1\}$, $Q \in \Gamma_\ell$ such that $g_\eta^{2n_2\ell}(y) \in f^{2n_2\ell}(Q)$. Note that if

$$|\log \det D f^{2n_2\ell}(y) - \log \det D g^{2n_2\ell}(y)| > K,$$

then the last conclusion of the proposition already holds for y .

Otherwise, since $g^{2n_2\ell}(y)$ belongs to $f^{2n_2\ell}(Q)$, we have

$$Dg^{2n_2}(g^{2n_2\ell}(y)) = Dg_Q^{2n_2}(g^{2n_2\ell}(y));$$

since f is a linear cocycle, we obtain

$$\log \det D f^{2n_2}(g^{2n_2\ell}(y)) = \log \det D f^{2n_2}(f^{2n_2\ell}(y)).$$

Thus the property satisfied by g_Q implies that

$$|\log \det D f^{2n_2}(f^{2n_2\ell}(y)) - \log \det D g^{2n_2}(g^{2n_2\ell}(y))| > 2K.$$

Using the fact that

$$|\log \det D f^{2n_2\ell}(y) - \log \det D g^{2n_2\ell}(y)| \leq K,$$

we then obtain that

$$|\log \det D f^{2n_2(\ell+1)}(y) - \log \det D g^{2n_2(\ell+1)}(y)| > K.$$

This gives again the last conclusion of the proposition and concludes the proof. \square

7 Almost tidy perturbation in a cube

The aim of this section is to give the proof of Proposition 6.6, which finishes the proof of Theorem A and hence of the Main Theorem.

This proposition is very close in spirit to the original idea of C. Pugh for the famous C^1 -closing lemma. Pugh wanted to perturb the orbit of a point x in a cube in such a way that it exits the support of the perturbation through the orbit of another given point y . Pugh noticed that, at each time, one has much more freedom to perturb the orbits “in the direction of the smallest dimension of the image of the cube”. As he needed to perform a perturbation in arbitrary directions, a linear algebra lemma allowed him to choose the pattern of the cube such that each direction would be at some time the smallest one.

Here we just want to perform a perturbation that modifies the jacobian: hence we can do it by a perturbation “in an arbitrary direction”. However, in principle our perturbations have to be tidy, or very close to tidy. For this reason the support of the perturbation will have length $2n_2$: we obtain the perturbation of the jacobian during the first n_2 iterates, and then try to remove the perturbation during the last n_2 iterates. For this reason, we need that the smallest dimension of the image of our cube corresponds to the same direction, all along the time support of the perturbation. This is obtained by choosing a pattern of our cubes having one direction much smaller than the others.

An additional difficulty comes from the fact that we were not able to obtain a tidy perturbation. After several iterations, the thin edges of the cube could become strongly sheared above its base; for this reason, it was not possible to remove the perturbation in a neighborhood of these edges. By choosing the cubes’s height small enough, we are able to remove the perturbation in a rectified cube which differs from the sheared one only in a small region (see Figure 2). This “almost tidy perturbation” turns out to be sufficient for our purposes.

Figure 2: The image of a cube under many iterates of a linear cocycle can be quite distorted (top). The image of a wafer, on the other hand, stays flat and wafer-like (bottom).

7.1 Choice of n_2

Given $d \geq 1$ and $\theta \in (0, 1)$, we fix $\theta_0 = \theta^{\frac{1}{3}}$ and choose:

- a smooth function $\zeta: \mathbb{R}^{d-1} \rightarrow [0, 1]$ such that
 - $\zeta(v) = 1$ if $v \in [-\theta_0^2, \theta_0^2]^{d-1}$ and
 - $\zeta(v) = 0$ if $v \in \mathbb{R}^{d-1} \setminus [-\theta_0, \theta_0]^{d-1}$;
- a smooth function $\xi: [-1, 1] \rightarrow \mathbb{R}$ such that:
 - $\xi(z) = z$ for $z \in [-\theta_0^2, \theta_0^2]$,
 - $\xi(z) = 0$ for z in a neighborhood of $[-1, 1] \setminus [-\theta_0, \theta_0]$, and
 - $\xi(-z) = -\xi(z)$.

We denote by X the vector field on $[-1, 1]$ defined by $X(z) = \xi(z) \frac{\partial}{\partial z}$ and by $(X_s)_{s \in \mathbb{R}}$ the induced flow on $[-1, 1]$. For every non-trivial closed interval $I \subset \mathbb{R}$ and any s , we denote by X_s^I the diffeomorphism of I obtained from X_s by considering a parametrization of I by $[-1, 1]$ with constant derivative.

Remark 7.1. The distance $d_{C^1}(X_s^I, \text{id}_I)$ has two parts. The C^0 part is proportional to the length of I . The part that measures the distance between the derivatives does not depend on I :

$$\max\{|D(X_s^I) - 1|, |D(X_{-s}^I) - 1|\} = \max\{|D(X_s) - 1|, |D(X_{-s}) - 1|\}.$$

We fix constants $C, \varepsilon > 0$ and a real number $s_0 > 0$ satisfying $\max\{|D(X_{s_0}) - 1|, |D(X_{-s_0}) - 1|\} < \frac{\varepsilon}{C}$. We then define the diffeomorphisms $h_s = X_{s, s_0}$ and $h_s^I = X_{s, s_0}^I$.

Fix $K > 0$. Note that the derivative of h_{-1} on $[-\theta_0^2, \theta_0^2]$ is a constant: it is equal to $e^{-s_\varepsilon} < 1$ for some constant s_ε . We fix $n_2 \geq 1$ such that

$$n_2 s_\varepsilon > K.$$

7.2 Construction of a perturbation

Consider now a sequence of matrices $(A_i)_{i \in \mathbb{Z}}$ in $GL(d, \mathbb{R})$ such that $\|A\|, \|A_i^{-1}\| < C$, and denote by f the associated linear cocycle. Up to a change of coordinates by isometries on each $\{i\} \times \mathbb{R}$, we may assume that the A_i leave invariant the hyperplane $\mathbb{R}^{d-1} \times \{0\}$ and take the form

$$A_i = \begin{pmatrix} & & \alpha_1^i \\ & B_i & \vdots \\ 0 & \dots & 0 & b_i \end{pmatrix}.$$

For $i \in \{0, \dots, 2^{d+1}n_2\}$ and $\mu > 0$ we set

$$I_i = \left[-\mu \prod_{k=0}^{i-1} b_k, \mu \prod_{k=0}^{i-1} b_k \right].$$

We next fix $j \in \{0, \dots, 2^d - 1\}$. For each $i \in \mathbb{Z}$, we denote by H_i the diffeomorphism of $\{i\} \times \mathbb{R}^d$ defined as follows:

- $H_i = \text{id}$ if $i \notin \{2jn_2, \dots, 2(j+1)n_2 - 1\}$.
- For $i \in \{2jn_2, \dots, 2(j+1)n_2 - 1\}$, the map H_i coincides with id outside $\{i\} \times \mathbb{R}^{d-1} \times I_i$.
- For $i \in \{2jn_2, \dots, 2(j+1)n_2 - 1\}$ and $(v, z) \in \mathbb{R}^{d-1} \times I_i$, we set

$$s(v) = \zeta \left((B_{i-1} \dots B_0)^{-1}(v) \right),$$

and define

$$\begin{aligned} H_i(v, z) &= (v, h_{-s(v)}^{I_i}(z)) \text{ if } i < (2j+1)n_2, \\ H_i(v, z) &= (v, h_{+s(v)}^{I_i}(z)) \text{ if } i \geq (2j+1)n_2. \end{aligned}$$

Note that the diffeomorphisms H_i depend on the choice of $\mu, (A_i)$ and j .

We define by g the cocycle that coincides with $f \circ H_i$ on $\{i\} \times \mathbb{R}^d$. It will satisfy the conclusions of Proposition 6.6, provided μ has been chosen smaller than some constant $\mu_0 = \min\{\mu_1, \mu_2, \mu_3, \mu_4\}$ which will be defined in the following subsections.

7.3 Support of the perturbation: first choice of μ

Let $\mathcal{C}_i = P_i \times I_i$ where $P_i = B_{i-1} \dots B_0([-1, 1]^{d-1})$. Let $Q_i = A_{i-1} \dots A_0(Q_\mu)$. The two parallelepipeds \mathcal{C}_i and Q_i have the same base $P_i \times \{0\}$ in $\mathbb{R}^{d-1} \times \{0\}$ and the same height along the coordinate z , but \mathcal{C}_i has been rectified.

In these notations g is a perturbation of f with support contained in $\bigcup_{i=0}^{2n_2-1} \{i + 2jn_2\} \times \theta_0 \mathcal{C}_{i+2jn_2}$.

Lemma 7.2. *Given $d, C, K, \varepsilon > 0$ and $\theta \in (0, 1)$, there exists $\mu_1 = \mu_1(d, C, K, \varepsilon, \theta)$ such that, for every $\mu \in (0, \mu_1)$, for every sequence (A_i) in $GL(d, \mathbb{R})$ with $\|A_i\|, \|A_i^{-1}\| < C$ and for every $i \in \{0, \dots, 2^{d+1}n_2\}$, we have:*

$$\theta_0 \mathcal{C}_i \subset Q_i.$$

In particular the perturbation g defined in Section 7.2 is supported in

$$\bigcup_{i=2jn_2}^{2(j+1)n_2-1} f^i(\{0\} \times Q_\mu) = \bigcup_{i=2jn_2}^{2(j+1)n_2-1} Q_i.$$

Proof. Choose

$$\mu_1 < \left(2^{d+1} n_2 C^{2^{d+2} n_2} \right)^{-1} (\theta_0^{-1} - 1).$$

Consider a point (v_i, z_i) in \mathcal{C}_i , and for $0 \leq k < i$, its image (v_k, z_k) under $(A_{i-1} \dots A_k)^{-1}$. We need to show that (v_0, z_0) belongs to $\theta_0^{-1} Q_\mu$.

For the second coordinate, we have $z_0 = z_i \prod_{k=0}^{i-1} b_k^{-1}$, and hence z_0 belongs to $I_0 \subset \theta_0^{-1} I_0$. It remains to control the first coordinate: for each k , it decomposes as

$v_k = B_k^{-1}v_{k+1} + w_k$ where w_k is the projection on the first coordinate of $A_k^{-1}(0, z_{k+1})$. Note that

$$\|w_k\| \leq C|I_{k+1}| \leq \mu C^{k+2} \leq \mu C^{i+1}.$$

Decomposes v_k as a sum $\tilde{v}_k + r_k$ where $\tilde{v}_k = (A_{i-1} \dots A_k)^{-1}(v_i)$ belongs to P_k and

$$r_k = \sum_{j=k}^{i-1} (A_{j-1} \dots A_k)^{-1} w_j.$$

We thus have

$$\|r_k\| \leq (i-k)C^{i-k-1} \max\{w_j\} \leq iC^{2i}\mu_1.$$

Since v_0 belongs to $P_0 = [-1, 1]^{d-1} \times \{0\}$, it is now enough to show that $\|r_0\|$ is smaller than the distance between the complement of $\theta_0^{-1}P_0$ and P_0 . This distance is bounded from below by $\theta_0^{-1} - 1$. Our choice of μ_1 now implies that v_0 belongs to $\theta_0^{-1}P_0$, as required. \square

7.4 Size of the perturbation: second choice of μ

We check here that the perturbation g is C^1 -close to f .

Lemma 7.3. *Given $d, C, K, \varepsilon, \theta > 0$ there exists $\mu_2 = \mu_2(d, C, K, \varepsilon, \theta)$ such that for any $\mu \in (0, \mu_2)$, for any sequence (A_i) in $GL(d, \mathbb{R})$ with $\|A_i\|, \|A_i^{-1}\| < C$ and for any $j \in \{0, \dots, 2^d - 1\}$, the diffeomorphisms f and g defined at Section 7.2 satisfy*

$$d_{C^1}(g, f) < \varepsilon.$$

Proof. We choose

$$\mu_2 < \frac{\varepsilon}{C^{2^{d+2}n_2} s_0 \|\xi\| \|D\zeta\|}.$$

For all $i \in \{0, \dots, 2^{d+1}n_2 - 1\}$, the quantity $\|DH_i(\frac{\partial}{\partial z}) - \frac{\partial}{\partial z}\|$ is bounded by the maximum of $|Dh_1 - 1|$ and $|Dh_{-1} - 1|$ and thus is bounded by ε/C , by our choice of s_0 . For any unit vector u of $\mathbb{R}^{d-1} \times \{0\}$ we have

$$\begin{aligned} \left\| DH_i \left(\frac{\partial}{\partial u} \right) - \frac{\partial}{\partial u} \right\| &\leq \|\xi\| \|D\zeta\| \|(B_{i-1} \dots, B_0)^{-1}\| s_0 \mu \prod_{j=0}^{i-1} b_j \\ &\leq C^{2(2^{d+1}n_2-1)} s_0 \mu \|\xi\| \|D\zeta\|. \end{aligned}$$

It follows that for $\mu < \mu_2$, we have $\|DH_i - \text{id}\| < \frac{\varepsilon}{C}$, and consequently we obtain $\|Dg - Df\| < \varepsilon$. \square

7.5 Perturbation of the jacobian: third choice of μ

We define the *effective support* of the perturbation as the set where

$$|\log \det Df - \log \det Dg| = |\log \det DH| = s_\varepsilon.$$

By construction, this effective support contains $\bigcup_{i=0}^{n_2-1} \{i + 2jn_2\} \times \theta_0^2 \mathcal{C}_{i+2jn_2}$. We now prove that for small μ the orbits of the points in $\{0\} \times \theta Q_\mu$ under g meet the effective support; this implies that the perturbation has the expected effect on the jacobian along these orbits.

Lemma 7.4. *Given $d, C, K, \varepsilon, \theta > 0$ there exists $\mu_3 = \mu_3(d, C, K, \varepsilon, \theta)$ such that for any $\mu \in (0, \mu_2)$, for any sequence (A_i) in $GL(d, \mathbb{R})$ with $\|A_i\|, \|A_i^{-1}\| < C$ and for any $j \in \{0, \dots, 2^d - 1\}$, the perturbation g defined at Section 7.2 satisfies for every $i \in \{0, \dots, n_2 - 1\}$:*

$$g^i(\{2jn_2\} \times \theta Q_{2jn_2}) \subset \{i + 2jn_2\} \times \theta_0^2 \mathcal{C}_{i+2jn_2}.$$

In particular, for every $x \in \{0\} \times \theta Q_\mu$ one has

$$|\log \det Df^{n_2}(f^{2jn_2}(x)) - \log \det Dg^{n_2}(f^{2jn_2}(x))| = n_2 s_\varepsilon > K.$$

Proof. The proof is quite similar to the proof of Lemma 7.2. We choose

$$\mu_3 < \left(2^{d+1} n_2 C^{2^{d+2} n_2}\right)^{-1} (\theta_0^{-1} - 1).$$

Let $(0, v_0, z_0)$ be a point in $\{0\} \times \theta Q_\mu$, and let (i, v_i, z_i) be its image under g^i . We will show that (v_i, z_i) belongs to $\theta_0^2 \mathcal{C}_i$, for every $i \in \{0, \dots, (2j+1)n_2 - 1\}$.

For the second coordinate, we have $z_i \leq z_0 \prod_{k=0}^{i-1} b_k$, since H_i is the identity, for $i < 2jn_2$, and shrinks the second coordinate, for $i \in \{2jn_2, \dots, (2j+1)n_2 - 1\}$. Hence z_i belongs to $\theta I_i \subset \theta_0^2 I_i$. It remains to control the first coordinate: H_i has the form $(v, z) \mapsto (v, h_i(v, z))$ and v_i decomposes as $B_{i-1}v_{i-1} + w_i$ where w_i is the projection on the first coordinate of $A_{i-1}(0, h_{i-1}(v_{i-1}, z_{i-1}))$. Note that

$$\|w_i\| \leq C \|h_{i-1}(v_{i-1}, z_{i-1})\| \leq C |z_{i-1}| \leq C^i \mu_3 \theta.$$

In particular, v_i decomposes as a sum $\tilde{v}_i + r_i$, where $\tilde{v}_i = B_{i-1} \dots B_0(v_0)$ belongs to θP_i and

$$r_i = \sum_{k=1}^i A_{i-1} \dots A_k w_k.$$

It follows that $\|r_i\| \leq i C^i \mu_3 \theta$.

Since \tilde{v}_i belongs to θP_i , it is now enough to show that $\|r_i\|$ is smaller than the distance between the complement of $\theta_0^2 P_i$ and $\theta P_i = \theta_0^3 P_i$. This distance is bounded from below by $C^{-i} \theta (\theta_0^{-1} - 1)$. Our choice of μ_1 now implies that v_i belongs to $\theta_0^2 P_i$, as required. \square

7.6 Almost tidy perturbation: fourth choice of μ

To finish the proof of Proposition 6.6, we are left to show that, after a rescaling by the linear map E_μ , the action of the perturbation g on the orbits of f tends uniformly to the identity as $\mu \rightarrow 0$.

Lemma 7.5. *Given $d, C, K, \varepsilon, \theta$ and $\eta > 0$ there exists $\mu_4 = \mu_4(d, C, K, \varepsilon, \theta, \eta)$ such that for any $\mu \in (0, \mu_4)$, for any sequence (A_i) in $GL(d, \mathbb{R})$ with $\|A_i\|, \|A_i^{-1}\| < C$ and for any $j \in \{0, \dots, 2^d - 1\}$, the diffeomorphisms f and g defined in Section 7.2 satisfy on $\{0\} \times \mathbb{R}^d$,*

$$d_{unif} \left(\text{id}, E_\mu^{-1} f^{-2(j+1)n_2} g^{2(j+1)n_2} E_\mu|_{\{0\} \times \mathbb{R}^d} \right) < \eta.$$

Proof. First of all, notice that:

- $H_i = \text{id}$ if $i < 2jn_2$ or $i \geq 2(j+1)n_2 - 1$,
- $H_i = (E_\mu \bar{A}_{i-1} \dots \bar{A}_0) H^{-1} (E_\mu \bar{A}_{i-1} \dots \bar{A}_0)^{-1}$ for $2jn_2 \leq i < (2j+1)n_2$,
- $H_i = (E_\mu \bar{A}_{i-1} \dots \bar{A}_0) H (E_\mu \bar{A}_{i-1} \dots \bar{A}_0)^{-1}$ for $(2j+1)n_2 \leq i < 2(j+1)n_2$,

where H is a diffeomorphism of $\{0\} \times \mathbb{R}^d$, and the \bar{A}_k are matrices, defined by

$$H(v, z) = (v, h_{\zeta(v)}(z)),$$

$$\bar{A}_k = \begin{pmatrix} & & 0 \\ & B_k & \vdots \\ & & 0 \\ 0 & \dots & 0 & b_k \end{pmatrix}.$$

In this notation, we can write

$$\begin{aligned} E_\mu^{-1} f^{-2(j+1)n_2} g^{2(j+1)n_2} E_\mu|_{\{0\} \times \mathbb{R}^d} &= E_\mu^{-1} \left(\prod_{i=0}^{2(j+1)n_2-1} f^{-i} H_i f^i \right) E_\mu \\ &= Q_l (P_{2n_2-1} H \dots P_{n_2} H) (P_{n_2-1} H^{-1} \dots P_0 H^{-1}) Q_r, \end{aligned}$$

where

$$\begin{aligned} P_i &= (\bar{A}_{2jn_2+i-1} \dots \bar{A}_0)^{-1} (\bar{A}_{2jn_2+i}^{-1} E_\mu^{-1} A_{2jn_2+i} E_\mu) (\bar{A}_{2jn_2+i-1} \dots \bar{A}_0), \\ Q_r &= (\bar{A}_{2jn_2-1} \dots \bar{A}_0)^{-1} E_\mu^{-1} (A_{2jn_2-1} \dots A_0) E_\mu, \quad \text{and} \\ Q_l &= E_\mu^{-1} (A_{2(j+1)n_2-1} \dots A_0)^{-1} E_\mu (\bar{A}_{2(j+1)n_2-1} \dots \bar{A}_0). \end{aligned}$$

Note that

$$E_\mu^{-1} A_k E_\mu \xrightarrow{\mu \rightarrow 0} \bar{A}_k.$$

This implies that P_i , Q_r and Q_l tend to I_d when μ goes to 0. As a consequence $E_\mu^{-1} f^{-2(j+1)n_2} g^{2(j+1)n_2} E_\mu$ tends uniformly to the identity on $\{0\} \times \mathbb{R}^d$ as $\mu \rightarrow 0$. This implies the conclusion of the lemma. \square

Appendix: The (LD) property is not generic

The proof of our main theorem would have been much easier if the large derivative property were a generic property; the aim of this section is to show that, indeed, it is not a generic property.

Consider the set $LD \subset \text{Diff}^1(M)$ of diffeomorphisms having the (LD)-property.

Remark 7.6. If f is Axiom A, then $f \in LD$. More generally, if the chain recurrent set $CR(f)$ is a finite union of invariant compact sets, each of them admitting a dominated splitting, then $f \in LD$: the dominated splitting implies that the vectors in one bundle are exponentially more expanded than the vectors in the other bundle, implying that $\sup\{\|Df^n(x)\|, \|Df^{-n}(x)\|\}$ increases exponentially with n for $x \in CR(f)$.

Consider the open set \mathcal{T} of *tame diffeomorphisms*: these are the diffeomorphisms such that all the diffeomorphisms in a C^1 -neighborhood have the same finite number of chain recurrence classes. A consequence of [BDP] and [BC] is that any diffeomorphism in an open and dense subset $\mathcal{O} \subset \mathcal{T}$ admits a dominated splitting on each of its chain recurrence classes. This implies that \mathcal{O} is contained in LD .

To find an open set in which LD is not residual, we therefore must look among the so-called *wild* diffeomorphisms, whose chain recurrent set has no dominated splitting.

Proposition 7.7. *For any compact manifold M with $\dim(M) > 2$, there exists a non-empty open subset $U_M \subset \text{Diff}^1(M)$ such that $LD \cap U_M$ is meager.*

Let V_M be the set of diffeomorphisms f possessing a periodic point $x = x_f$ such that $Df^{\pi(x)}(x) = id$, where $\pi(x)$ is the period of x . We denote by U_M the interior of the closure of V_M . In [BD], it is shown that U_M is nonempty, for every compact manifold M of dimension at least 3.

Remark 7.8. The least period of x_f is not locally bounded in U_M . This is because, for every $n > 0$, the set of diffeomorphisms whose periodic orbits of period less than n are hyperbolic is open and dense.

To prove the proposition, it suffices to show that $LD \cap U_M$ is meager.

For every $K > 1$ and $n \in \mathbb{N}$, we consider the set $W(K, n) \subset \text{Diff}^1(M)$ of diffeomorphisms f such that there exist $m > n$ and two compact balls B_0, B_1 with the following properties.

- B_1 is contained in the interior of B_0 ;
- $f^m(B_0)$ is contained in the interior of B_0 , and B_1 is contained in the interior of $f^m(B_1)$;
- for every $x \in B_0$:

$$\sup\{\|Df^m(f^j(x))\|, \|Df^{-m}(f^j x)\|, x \in \Lambda_f \text{ and } j \geq 0\} < K.$$

Note that $W(K, n)$ is an open set, for every K and n . Furthermore, for a given $K > 1$, the diffeomorphisms in $\mathcal{R} = \bigcap_{n \in \mathbb{N}} W(K, n)$ do not satisfy the (LD) property.

To see this, let $f \in \mathcal{R}$, and fix an arbitrary integer $n > 0$. Consider an integer $m > n$ and two balls B_0, B_1 given by the definition of $W(K, n)$. Then the points in the open set $\text{Int}(B_1) \setminus f^{-m}(B_1)$ are not periodic, since their entire orbits lie in B_0 , and along these orbits, the quantities $\|Df^m\|$ and $\|Df^{-m}\|$ are bounded by K . Hence f does not satisfy the (LD) property.

Lemma 7.9. *For every $K > 1$ and every $n \in \mathbb{N}$, $W(K, n) \cap U_M$ is (open and) dense in U_M .*

Proof. Consider $f_0 \in U_M$, and let $\mathcal{U} \subset U_M$ be a neighborhood of f_0 . There exists $f_1 \in \mathcal{U}$ and $m > n$ such that f_1 has a periodic point x of period m with $Df^m(x) = \text{Id}$. Then there exist $f_2 \in \mathcal{U}$, arbitrarily close to f_1 , and a small ball D contained in an arbitrarily small neighborhood of x such that $f_2^m(D) = D$, the restriction of f_2^m to D is the identity map, and $f_2^i(D) \cap D = \emptyset$ for $i \in \{1, \dots, m-1\}$. Let $\Delta = \bigcup_0^m f_2^i(D)$.

Observe that there is a neighborhood $\mathcal{U}_1 \subset \mathcal{U}$ of f_2 such that $\|Df^m\|$ and $\|Df^{-m}\|$ are bounded by $\frac{1}{2}K$ on Δ . We conclude the proof by noting that there exist $f_3 \in \mathcal{U}_1$ and two compact balls $B_1 \subset \text{Int}(B_0) \subset B_0 \subset \text{Int} D$ with the desired properties. \square

B. Fayad has observed that, for the proof of the Main Theorem, it suffices to obtain the (LD)-property merely on a dense subset of M . This weaker (LD) condition is not residual either: the proof of the proposition above shows that for the diffeomorphisms in the residual subset \mathcal{R} , the (LD)-property is not satisfied on any dense subset of M .

We conclude this section by discussing another strange feature of the (LD) property: we have proved the density of the set of diffeomorphisms satisfying the large derivative property and whose periodic orbits are all hyperbolic. On the one hand, the large derivative property is a uniform property on the non-periodic orbits (in the definition, the integer $n(K)$ does not depend on the point x). On the other hand, for the hyperbolic periodic orbits, the norm of the derivative tends exponentially to infinity. So it is natural to ask if we could also include the periodic orbits in the definition of (LD)-property. Let us say that f satisfies the *strong (LD) property* if, for every $K > 1$ there exists n_K such that for every $n \geq n_K$ and every $x \in M$ one has $\sup\{\|Df^n(f^i(x))\|, \|Df^{-n}(f^i(x))\|, i \in \mathbb{Z}\} > K$.

Question 6. *Does the strong (LD) property hold on a dense subset of $\text{Diff}^1(M)$?*
